Slow Code, I think it is time you put up or shut up. If the skills among you dinos were so great, then you had to finish at the top of your category. So tell us now, what group were you part of, what section, and what category did you compete in?

Then, when the results are published, we will compare your standings with those other groups who had the modern, technically trained operators.

We'll see if the dinos are extinct or if modern humans have triumphed.

From: ml <m@di.net>
Message-ID: <m-4CB295.22423530062006@news.verizon.net>
Source record: 56843

hi

If you buy a length of coax w/connectors on it , either a short jumper
say 3ft or a run of say 100ft

what is an easy way to test the coax as well as the quality of
termination connector quality?

accuracy is what i am looking for to ensure realibility at 1gig

thanks

If you "weigh" 200 lb (no s at the end of unit symbols) on Earth, that _is_ your mass, in normal usage in either the medical sciences or in sports, which are of course the purposes for which we normally weigh ourselves.

You can, of course, use those 200 pounds in the F = ma formula. For example, if you accelerate those 200 pounds at 40 ft/s², the force is 8000 lb·ft/s², which is, of course, 8000 poundals, since a poundal is the force which will accelerate a mass of one pound at a rate of 1 ft/s².

> weight on the moon.

Not at all. It indicates that you exert a force due to gravity of 1050 poundals (not lbs) on the moon. On Earth, you would exert a force of somewhere in the neighborhood of 6410 poundals to 6450 poundals, depending on your specific location.

Not only is it just as easy to use an unfamiliar unit for force as it is to use some strange unit for mass, but the absolute foot-pound-second system (which includes poundals) has been around considerably longer than the gravitational foot-pound-second system (which includes slugs), and rather than either of those systems, those still using English units are more likely to use the engineering system which includes both pounds and pounds force, but neither slugs nor

poundals. Since that system is not a completely coherent system, of course, many of the formulas need to be adjusted with a g_c factor, a dimensionless number equal to the ratio of the acceleration used to define a pound-force to that used to define a poundal, or g_c = (32.174 ft/s²)/(1 ft/s²) = 32.174

> In the non scientific world, where the metric unit KG is used for
> weight, M=F*A works just fine if you put what you call "weight" in KG in
> for M in the formula.

The symbol for kilograms is kg, not KG. There is nothing different about the weight in the English units world, where the pound used for this purposes is, by definition, exactly 0.45359237 kg.

Message-ID: <g3bhn3-21f.ln1@p400bob.personal.cox.net>
Source record: 56845

Easy way to gte a rough idea is to measure the power of your TX at the
TX output, then connect the coax and measure the power at the end of it.
The loss/diff should be a published figure that is frequency dependent.
If the loss exceeds the published number you have to suspect the
cable/connectors.

Cheers Bob

Pounds ALWAYS WERE units of mass.

Consider that the slug is a little-used 20th century invention, one which was not used to any significant extent anywere until after 1940, and after a couple of decades has pretty much disappeared from most textbooks again along with the rest of the English units.

Don't you think physicists and engineers using English units ever has occasion to deal with the quantity called mass before then?

The normal English units of mass, in our everyday lives, are pounds and ounces and tons and the like. (Even bushels, to a farmer and on the commodities markets, are units of mass, not of volume.)

Slugs are only used in calculations, and only exist in a particular coherent system of units used for that purpose, one which not only doesn't include pounds as units of mass, but also doesn't include any Btu or psi nor even any ounces or inches or miles.

That gravitational foot-pound-second system, however, is only one of several such systems which can be used. There are no slugs in a gravitational inch-pound-second system of units, and there are no slugs in the absolute foot-pound-second system of units, to name a couple of the other systems.

That absolute foot-pound-second system of units is, of course, considerably older than the gravitational system which includes slugs. It dates back at least to 1879. In that system, the poundal is the derived unit of force, the force which will accelerate the base unit of mass at a rate of 1 ft/s^2.

So what exactly was the BASE UNIT OF MASS in this older absolute foot-pound-second system, which was around long before anybody ever used a "slug" as a unit of mass? Hint: It is the "p" in this fps system.

10. HFTA-ARRL-Space

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-01 15:09:22 UTC
From: jawod <jawod@fuse.net>
Message-ID: <52ec8$44a69065$453d9423$8142@FUSE.NET>
Source record: 56847

Tried to make the subject grab a bit.

I just fininshed the ARRL Antenna Book Chapter on Effects of Ground.
There are HFTA graphs showing elevation response for various antenna
configurations (mostly Yagis).

Most arrays show good response up to 12 degrees above the horizon, then
many show a null and then, a second peak around 25 to 30 degrees above
the horizon.

Here's my question:
At 25 to 30 degrees elevation response, aren't these waves leaving the
ionosphere (i.e., refracted instead of reflected)?

Am I right to consider this component of propagation to have left the earth?

This would indicate a substantial fraction of each amateur transmission
is sent into space.

I always thought Broadcast transmissions were most likely to emanate
from Earth. Are hams more or less likely to transmit into space than
Broadcast?

John
(who wishes to remain a student and never an expert)

When I was in the Air Force the DDRR antenna became the topic of discussion of many of us who were hams or wanted to become hams at the time. Someone had read a little about it and decided this must be the end-all of antennas. A little more research revealed that this antenna truly had a lot of the attributes my friend claimed but it was also an extremely low impedance antenna(less than an ohm if memory serves). This means the elements would have to be built to handle high currents and the matching networks could be a real problem. All of this meant lots of money to build so it was deemd impratical.

In your HFTA program run the antennas at various heights. Amongst
other things,varying the height of the antenna will change the
elevation angle of the lobes.

Regarding a new philosophy for constructing shortened antennas.

Have somebody experience with Distributed Loaded Monopole-technology
based antennas.

Please look on slide number 10, 19, 24, 53:
http://www.uri.edu/news/vincent/boxboro_files/frame.htm

Slide 25 shows how it is constructed:
http://www.uri.edu/news/vincent/boxboro_files/frame.htm

According to the following test, the antenna should be good - and maybe
better than other shortened antennas. 70% efficiency for a 1/4 wave
shortened antenna, is that good?:

-

April 28, 2005 Navy gives URIï¿½s small antenna big results
http://www.uri.edu/news/releases/?id=3126
Quote: "...
In addition, the gain of Vincentï¿½s capacity Top Hat DLM antenna, which
incorporates a helix, a load coil, a capacitive top hat utilizing radial
spokes at the top of the antenna and a horizontal plane was nearly
identical to the ideal quarter wave antenna. Its bandwidth was greater
than 5 percent of the operating frequency and the antenna is more than
70 percent shorter than an ideal quarter wave antenna.

Vincentï¿½s standard DLM antennas with a standard helix and load coil were
also tested at various frequencies. All exhibited gains nearly equal to
the ideal antenna with bandwidths of 3 to 10 percent. The antennas were
33 to 40 percent shorter.

Hi John,

You are confusing models of propagation with models for antenna lobe characteristics. The lobes certainly have a major impact on propagation, but the antenna modeler is not concerned with that. The terrain modeler is not a propagation modeler. For that, consult VOACAP or WINCAP. They are properly concerned with ionospheric issues, but they are also driven by antenna models too.

>Am I right to consider this component of propagation to have left the earth?

To some degree, yes, but it has very little bearing on what you are focused on here.

>This would indicate a substantial fraction of each amateur transmission
>is sent into space.

In fact, no. The apportionment of the energy into lobes is simply robbing Peter to pay Paul. The nulls were developed from energy lost to the peaked lobes. This is very loose analogy because energy was never lost, it is merely the combination from many sources that makes this lobe shape appears as it does.

An antenna radiates from every portion of its structure and in every direction. When all contributions are viewed from a distance, some portions of the structure are out of phase with respect to others portions. When those two contributions are 180ï¿½ out of phase, that remote point at where they combine perceives a null (a destructive combination). At some other remote point, those same two contributions may combine constructively for a peak response. Same energies all around, but path lengths shift the wave phases and how they combine constructs the characteristic lobe shape.

If you took college physics, you must have seen how two charges separated by a distance combine their effects at remote points to offer an "electric dipole." Same logic.

Whether you call it Refraction or Reflection hardly matters.

What matters is that the wave, in effect, is reflected from an ionospheric layer at at a particular height, roughly according to optical laws. Trigonometry Rules!

Since the transmitted 'beam' has a very wide angle in the vertical plane, the energy returns to earth over an even wider range of distances.

The 'elevation angle' reported by antenna simulation programs is not very meaningfull. It contains very little useful information, mainly because the height of a reflecting layer is unknown at the time of transmission. Neither is the number of hops known to a particular destination.

Reg.

Hi Glenn,

The term here that seems to fit is poser. It is a variant of poseur
if that term is more familiar. This
>Test Report of U.R.I. DLM ANTENNAS
>By The NAVAL UNDERSEA WARFARE CENTER Of Newport, Rhode Island At The
>NUWC Fishers Island, New York One MileTest Range March 31, 2005.
is notable for having no signature page showing its bona fides. A
University of Rhode Island grade two technician is NOT an authority at
that facility.

Both the "report" and the other links all show very poor skills at
writing much less reporting. For instance, the "report" completely
omits the characteristic Z of the antenna. Is this antenna range
facility so shy of equipment that this notable specification was left
unmeasured? Even a standard quarter wave radiator is not a 50 Ohm
match.

This, and the rambling style that wanders the landscape in describing
this invention hardly inspires confidence in this moonlight episode of
using those facilities on the sly.

Hi Reggie,

I reserve that for the technical Falstaffs.

>Inapropriate for technical matters.

Their usual plea is
"discretion is the better part of a direct answer...."

As such, technical matters are notably absent, or at best serving as a
stalking horse. For those who are shy in their English skills,
"stalking horse" finds its current usage in "trolling."

That antenna *would* work okay with ladder line, and a tuner that could
handle the same.

I decided to do something really radical. I just sent off an email to
BuxComm to ask just what type of antenna it is....

that is a function of height. the main lobe from the antenna is aimed at the horizon and there are other lobes from the design of then antenna. then reflections from the ground cause more vertical variations. these are dependent on the height and the terrain around the antenna.

>
> Here's my question:
> At 25 to 30 degrees elevation response, aren't these waves leaving the
> ionosphere (i.e., refracted instead of reflected)?

not necessarily. look at the arrival angle statistics and you will see that frequently very high angle propagation is possible. usually higher angles mean shorter distances but at times you can get many short high angle hops to cover long distances also.

>
> Am I right to consider this component of propagation to have left the

> Broadcast?

broadcast is more likely. there are many more broadcast stations on the air 24x7, over the same range of spectrum that we use, and running much higher power than we use. the most likely signals to reach out from earth are likely fm broadcast and tv signals since those are normally well above the critical frequency that reflects from the ionosphere and can be fairly high power. lower hf, mf, and lf are less likely to get out as they reflect from the ionosphere even at very high angles.

Dear John:
If you were a radio amateur who is interested in working other radio amateurs at a great distance, then you wish to have a significant portion of your antenna's radiation within about 12 to 2 degrees above the horizon.

In tern, this goal suggests that a preferred height for an HF, horizontally-polarized antenna is between 2 and 2.5 wavelengths above ground.

If the higher angle radiation does not pass through the ionosphere, it contributes to interference to (relatively) nearby stations (and, because the antenna probably is used for reception, contributes to hearing nearby stations). Expensive HF antenna systems exist that significantly suppress all except the lowest lobe.

If you wish to be a student of antennas, do invest in Kraus' 3rd edition of Antennas. Read and study the book starting with the first chapter.

Regards, Mac N8TT

Even if only three contacts are made, the score isn't what's important.
What is important is showing and training new hams in how to communicate
and operate effectively during emergencies and not be Appliance operators.
Hams like you that worry about final score are more likely to cheat
because you choose to ignore or fail to see the things that are important.

Reg,
Thanks for your answer.

I guess I was trying to get at how much ham radio is propagated into space. Certainly SOME does.

How does this compare to that amount propagated into space by Broadcast?

My assumption has been that VHF TV, etc is easily passed through the ionosphere (minimally refracted).

Radar is the best we do, but not much information is transmitted beyond
the fact that we are here, the beam is usually narrow, and the direction
varies quickly. EME is a distant 2nd, carries real information in
simple codes, the direction varies slowly, the beamwidth is usually low
(on high GHz bands it can be less than the width of the moon), and the
number of transmitters is very low.

Either one of the previous could be picked up from a fair distance, but
not likely because of the narrow angles and varying direction. And
commercial broadcasting doesn't have the ERP in any particular direction
to carry far. We live next to a very large noise source that would tend
to swamp out what we generate.

VHF and UHF emissions escalated rapidly after WWII with the popularization of TV, and these readily penetrate the ionosphere. So there's a sphere of such emissions radiating outward from the Earth at the speed of light. And at the leading edge of this radiation sphere are the McCarthy hearings and the Howdy Doody show. No wonder the ETs have left us alone!

To: "Richard Clark" <kb7qhc@comcast.net>
Subject: Please Post in rraa
From: "Walter Maxwell" <walt@w2du.com>
Date: Sat, 1 Jul 2006 17:31:29 -0400

Richard, I've been trying to post the msg below to the HFTA-ARRL-Space
thread, but after three attempts to send it it doesn't get posted.
Would you please post it for me in the spot following Mac's?

Walt, W2DU

Hello John,

I believe your other respondents missed one of your points concerning
reflection and refraction, and therefore didn't respond completely to
it.

Whether reflection, refraction, or total penetration of the ionosphere occurs depends on the ionospheric layer, the time of day that determines the sun angle on the layer, the resulting level of ionization, the angle the ray makes on incidence with the layer, and the frequency of the energy in the arriving ray.

Consequently, the answer is complex. As we know, when the frequency is high enough (VHF and above) the result is total penetration--no reflection or refraction--line of sight reception only.

On the other hand, at HF the ratio between reflection and refraction varies. There are times when both occur. During those times the portion of the incident ray that is reflected returns to earth, while the portion that is refracted continues on through the ionosphere into space and never returns. I'm not sufficiently knowledgeable on the subject to go into further detail, but now that they've been nudged, either Richard C or Reggie can. Or someone else more knowledgeable than I.

Walt, W2DU

I call B.S.! If you old, outdated methods of communication are so superior, then you should have locked up the contest.

So, this means one of two things. 1.) you're not telling the truth, or, 2.) the old methods you claim are superior are really not and the new "appliance operators" at other clubs using modern methods kicked your collective butts.

I suspect that 1. is the truth and you did not participate in FD and didn't teach any news hams anything. In fact, if you did participate in FD, the "appliance operators" probably ran rings around you and embarrassed you so bad, you had to create this story to save face.

Nice try, no one is buying the BS.

Hi John,

Perhaps you should offer that definition as its application seems to
be quite rare, and paired with some obscurity to the world of
sub-atomic dispersion.

>I guess I was trying to get at how much ham radio is propagated into
>space. Certainly SOME does.

SOME about covers it (you want that specified in dB?). I suppose by
your other references to SETI you are wondering about the chances of a
QSO in the same frequency from the other side of that ionospheric
curtain.

Given the odds, one frequency is as good as the next....

>How does this compare to that amount propagated into space by Broadcast?

There you have to consider the magnitude of flux, continuously, over
the years. If the broadcasting is from Fox news (or any Murdoch
source for that matter), it will be indistinguishable from pinko
noise.

"Easy" and "accuracy" may not both come in the same package. Bob Bob is right but you could also do a swept VSWR. In my experience, it involves a device called a network analyzer, which sweeps across the band of interest through a directional coupler at the near end of the cable, into a dummy load at the far end. It automatically samples the reflected power and compares it to the forward power to produce the SWR more or less continuously. (I believe the sweeping is done incrementally, with steps so small it _appears_ continuous.)

The resulting info is plotted or displayed as a graph with frequency left-to-right and VSWR up-and-down, with 1:1 being on the bottom. Some cable is sold as being "100%" sweep tested" to some upper limit.

Last year I had a case of a Navy shipboard satcom uplink transmission line that failed its sweep test at one spot near the upper end of the frequency range ... around 8 GHz. We had to replace it. (AN/WSC-6, for those who know what that is.) We had the contractor "shoot" it three different times with different test equipment each time -- always the same. The new line was fine. Until then, I had never seen a defective cable that was quite so frequency sensitive!

no, it is actually a refraction. but it is useful sometimes to model it as
a reflection from a slightly higher level. that makes computation of angles
of incidence and height a bit easier.

==========

The trigonometry is quite simple. Things become complicated when the reflecting layer is not horizontal, ie., the layer is tilted.

The angle and direction of tilt are very difficult to predict. Consequently, where on the surface of the Earth a ray returns is anybody's guess.

This makes the vertical take-off angle, reported by antenna modelling programs, even less useful.

Reg.

==========
If the current RF power output itself is not a problem ,but the max
current which can be supplied by the power supply unit (presumably
13.8V) I would suggest to put a sealed (car) battery in parallel.

The quoted 150W RF power is highly likely PEP ,so when operating SSB the
average current consumption is possibly half the peak current or less
even with some speech compression .
The battery will happily supply some of the current during peak demand.

Since the battery is permanently 'on the charger ' being in parallel
with the power supply unit , you don't need a deep cycle battery ; a
cheap and cheerful 40 -60Ah sealed car battery will do the job well.
It is essential to put a 25-30 A fuse in series with the battery .

Note : I recommend anybody to use a (sealed) battery and a low power PSU
to feed a transceiver requiring (13.5 -13.8 V-DC) external power.
During rx periods the PSU output could be (automatically) disconnected .
Receiving on battery power alone is often beneficial eg less noise and
mains borne interference. Although the low impedance of the battery
will cause it to 'kill' most external mains borne interference already.

A local ham uses a FT857 with a 110Ah sealed battery, without a mains
fed PSU . When not operating the battery is connected to an automatic
car battery charger ,which is only disconnected during operation.

no, it doesn't make it less useful. as a statistic it is still good, but
you have to remember that it is nothing more than a statistic. and everyone
knows 'you can prove anything with statistics'. the fact that the
ionosphere is more complicated than a horizontal reflection layer model
represents doesn't mean that its usefulness is reduced, just that there are
some cases when it won't be completely accurate... those are the fun things
that happen with propagation that keep it interesting.

> work any other way.

Bullshit.

Here are a couple of other ways that work just fine with FFU:

200 lb * 32.2 ft/s² = 6440 pdl

0.52 slinch * 386 in/s² = 200 lbf

Be sure to distinguish pounds force (lbf) from pounds (lb), and units
of measure should remain unchanged in the plural, without adding any
language-specific "s" or whatever.

I inquired about the baluns on their wire antennas -- their antennas
feature 4-1 or 6-1 baluns, and got the following answer:

"There are NO RESISTORS, and our 4:1 BALUNs are CURRENT Balun.

As a matter of fact, all our baluns are CURRENT type. We also
make voltage baluns, however, they are sold on a per/order basis."

My mobile whip is probably that good on 20m up...
One note....Myself, I think using gain numbers to compare
verticals that are 1/4 wave or less is sort of silly. It's not the
gain that matters. It's the overall system efficiency that really
matters. And yes, 70% is fairly decent for a "short" vertical.
It's enough to not be able to tell a large difference from a full
1/4 wave.

Something else possibly interesting

I use to work for a company that amongst other things installed mobile phone base systems. One of the mandatory tests was to sweep the coax from the TX end after it had been terminated to the antenna. Return loss (SWR) was the major criteria for the test pass but it also showed the location of the impedance discontinuity. (ie in metres from the feedpoint) In most cases this was a cable indentation where it wasnt unwound from the drum carefully, or where the coiled stuff had been laid down flat instead of being kept vertical. (ie was distorted by its own weight) We did have a few cases however where the inside of the inner core had slight amounts of corrosion causing the problem. This was commonly LDF4-50 or LDF5-50 (foam coax a little less and a little more than 1" dia and had an inner core "pipe" with an inside air space.

Cheers Bob

A fast A/D front end on a PC, sampling at a minimum of 8MHz. Use the PC
as a DSP engine. I suspect that these would be available as a plug in
PCI card...

You can get an idea of what this is about by the plethora of sound card
based analysis systems now available (with a max sample rate of 44kHz or
thereabouts. Depending what you are doing and are real stingy a computer
controlled HF receiver and the soundcard interface might do it for you too.

Wanna be a bit more specific of your requirements and application?

Here are a couple messages I posted on eHam net. Any comments would be appreciated.

Thanks,

Doug VE3XDB

--
MESSAGE #1:

Hi everyone,

I am thinking of building a center loaded fan dipole. One wire dipole to cover 20 and 40 metres, and a second wire diple, connected at the same feedpoint, to cover 30 and 17 metres. Coils would be placed at the resonant point of the higher frequency, acting as both an RF choke and a loading coil. My question is this. I would like to have the wire beyond the coil as long as possible, but would still like the coil to have enough inductance to act as an effective RF choke for the higher band.

Other than through experimentation, how would one calculate or determine this mix of inductance/length?

Best regards,

Doug VE3XDB

--
MESSAGE #2:

Thanks for your replies. I know the technique does work. The Alpha Delta DX-CC puts a loading coil at the end of a 40 meter dipole, and adds about 9 feet of wire past the coil. This creates a dipole that resonates on 40 and 80 meters. Here is a link:

http://www.alphadeltacom.com/pg1.htm

As well, coil loaded HF antennas are described in "The Radio Amateur Antenna Handbook" by Bill Orr W6SAI and Stuart Cowan W2LX (Published in 1993 by Radio Amateur Callbook, a Division of BPI Communications Inc., pages 147 to 151).

Typical dual band antennas, of the type used for 2 meter/70 cm operation mobile are coil-loaded whips. Reg G4FGQ wrote a program called LOADCOIL.EXE that calculates the characteristics of a loading coil at any point on an antenna radiator of a given length.

I know the length of wire necessary to resonant the antenna at the higher frequency, and can figure out the coil required based on the length of wire past the coil. What I don't know is what is the maximum wire length, and therefore minimum inductance, necessary to have the antenna resonate on 2 bands.

Here is what I calculated, using Reg's program.

20-40 meter combination (resonant at 14.150 and 7.150 MHz)

Feedpoint to coil 16.54'
Coil 17.73 uH
Coil to end of antenna 7.46'

30-17 meter combination (resonant at 10.120 and 18.100)

Feedpoint to coil 12.93'
Coil 11.21 uH
Coil to end of antenna 5.07'

This creates an antenna that is about 75% full size on 30 and 40 meters, full size on 17 and 20 meters.

What I'm trying to determine is the maximum length of the radiator (and minimum inducatance) necessary to achieve dual band capability.

Any insights?

Best regards,

Doug VE3XDB

you don't want to think 'loading coils' you want to think 'traps'. they are two very different animals. loading coils are simply inductors that make the wire look longer electrically so you don't need as much room. traps are resonant circuits that exhibit a very large impedance at their tuned frequency so that it cuts off part of the antenna. usually you use a trap for multi-band dipoles, the first trap out from the center is tuned to cut off the outside of the element at the highest frequency, and then at lower frequencies it looks more like a small inductor so helps a bit as a loading coil on the lower band.

I believe EZNEC will model this but any modeling software is going to require a good deal good deal of tinkering when ported to real life with so many lumped circuit variables.

Placing the coils at the end of an otherwise resonate section seems like a good idea but it just is not that simple. The 40 meter operation will essentially be a center loaded dipole.

If you choose to go this direction I would think it best to do one dipole pair at a time. Also, study the commercial products carefully.

My preference would be four dipoles (one for each frequency) in a fan arrangement.

58. Help with NASA / Canaveral helicopter yagi antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-03 00:22:31 UTC
From: Robert Haston <rehaston@earthlink.net>
Message-ID: <brZpg.1918$ye3.1577@newsread1.news.pas.earthlink.net>
Source record: 56745

I am a pilot in the 301st Rescue Squadron at Patrick AFB, south of Cape Canaveral. We use helicopters to clear boats out of the Space Shuttle and Rocket danger zones off the coast.

I've bought some marine band 161-162 MHz (87 & 88 marine band) Automated Identification System (AIS) receivers to receive data transmissions from larger vessels. To maximize the reception of targets up to 60 miles out, I need a somewhat directional antenna, say a 2 or 3 element yagi.

The belly of our Blackhawk variant Pavehawk helicopters offers a mount and a 7 foot wide ground plane via the cargo hook on its belly. I can make the mount sideways and reversible so we can track big boats coming at us from the poles while we work all the little sport fishermen that infest the narrow east west azimuth out to 50 miles.

What I would like to do is use half of an antenna and use the aircraft as a ground plane to give us more ground clearance and less drag.

Here are my questions:

1. Can you use a yagi with elements only on one side when you have a ground plane just like a quarter wave dipole?

2. Would the 17" square hole that the antenna sticks out in the belly of make much of a difference in the ground plane? (this could be remedied).

3. For maximum gain, what needs to be grounded to the helicopter if anything: non radiating elements, the receiver, etc.?

4. What effect does diameter or material of elements have. I figure I can chop down car antennas (my present dipole) which are very cheap and sturdy enough to take 170 MPH winds.

5. What are good sites on making the right antenna?

Thanks,

I'll be happy to exchange lots of images of the equipment in action in exchange.

```
NEC indicates the input impedance is about 18 ohms for the 40 m model.
The gain (with ten 12 ft radials, base 3" above average ground) at
30 deg elevation angle is -3.9 dBi. I used a distributed helix with the GH
card,
but for the 2nd inductor a lumped element inductor, Q = 300. The value
for the 2nd inductor was much higher than the recommended 15 uH. at
about 36 uH.

An unloaded monopole of the same height, same radial system, has a gain
of -2.9 dBi at 30 deg elevation angle. Input impedance 6.2 - j748.
A two element matching network, inductor Q 400 (same Q as the
base helix) has a loss of 1.7 dB for an overall gain of - 4.6 dBi
```

at 30 deg.

Google Earth will give you the coordinates of a point anywhere. There are lots of free ways to convert lat long to bearing such as trigonometry spreadsheets - or a GPS.

Also, the FCC lists stations by lat/long.

Regardless of what you do, this is going to be guaranteed to have lousy bandwidth on 40 meters (and 30, but you don't care). The whole thing might be easier if you have 4 dipoles at a common feedpoint. I haven't tried 4, but did have 3: 40, 17, and 12 meters. You will want to have angular separation between the dipoles, either horizontal or vertical, or a combination. I did not measure it, but probably had about 15 degrees of separation. Tune by trimming the lowest frequency antenna first.

If you still want the trap dipoles, you can always buy the traps from places like AES. They will probably come with instructions. With 2 trap dipoles at a common feedpoint, I suspect this will be very difficult to tune.

Specifically, the application is one which uses a HAM radio transciever utilizing approx 20W-100W power and a Class E transmitter to drive data signals and power from an external coil to a series of smaller receiver coils which are implanted in biological tissue for biomedical application. I have to police/enforce the research personnel to ensure limits regarding std practices are not exceeded in regards to duration and length of RF exposure fothe patient. Of course I need to do this independently, because in this situation relying on their "good word" or verbal agreement isn't sufficient. I have to be able to be able to 1.) determine if there is a 570Hz to 4MHz signal present, and 2.) determine if it is encoded or modulated to carry the power and data signals. Not up my alley exactly, but I need to get it done. If there is an expansion card or USB interface device for PC, that would be preferable to aquiring an entire HAM rig. Any help appreciated. - Lars

I'm obviously not explaining myself very well. I'm not trying to say I have come up with some new revolutionary way to determine what heading some place is from you. The ways of doing that are endless. Which one is best, depends on the situation. Sure there are a number of places you can purchase a map and draw radials on it. However the chances of getting one that covers the area you want it to and having it centered where you want it aren't very good. Drawing all that on a map by hand is just way too much work if you ask me. I just think it is kind of cool to have a large map hanging on my wall centered at my location with radials going out. But hey I just like maps, guess that makes me weird.

i wouldn't touch something like this with a ham tranceiver. not enough control or calibration.

also, now you are talking of 2 different things. a transmitter that is sending the data/power, and your need to monitor for the presence of a signal independently. for monitoring for the presence of a signal across a bandwidth like that (really 570hz or is that 570khz??) you need something like a spectrum analyzer with an appropriate wide band antenna, go check with some emi testing labs for the type of equipment they use. you will quickly learn that unless you are doing this in a shielded room there are LOTS of signals in that range that will show up.

you also need to better state your requirements... 'duration and length' of exposure are the same thing and do not describe the whole problem. you must also measure the field strength (probably at a couple of locations) and frequency in addition to time. it sounds like you are not familiar enough with the terminology, equipment, or methods, to take on such a job that could be related to safety... get professional rf safety help NOW or you may need a professional lawyer in the future.

Source record: 56755

Dear Reg:

You have articulated one of the many reasons why HF propagation is described in stochastic terms. As you know very well, measurements or predictions comprise at least two numbers: the best estimate of the number and an estimate of the uncertainty of the first number. Present models of HF propagation, which include antenna characteristics, provide both numbers. Early models of HF propagation tended to be somewhat deficient in providing the second number.

However, I remember using the early models to predict (extrapolate) in real-time how much longer a certain frequency was likely to remain usable from noting the drop-out of a higher frequency. The physics involved has been understood for many years. It takes a long period of data gathering to be able to do a good job with the second number.

In the early days (post WW2) of radio astronomy, the uncertainties of some important measurements were greater than the estimate. That did not last.

This looks like an interesting project! Not quite what I was thinking in my original answer. I think your requirement is a lot simpler and cheaper.

A yes no indicator for RF between 570Hz and 4Mhz should be relatively easy, especially if it is a large signal in comparison to the ambient level. You could probably do it with a band pass filter network, a few transistors and some kind of display device (eg a LED). Some sensitivity calibratation over the freq range will need doing and maybe a subsequent adjustment to the BPF.

Determining if it is encoded depends on how it is encoded. If it creates pulses of a known PRF then a simple AM receiver to detect the envelope, followed by whatever ever band pass at the PRF and a subsequent display device. I cant comment on this further without knowing how you modulate.

Both circuits could be mounted in a box with an "RF detected" and "Modulated signal detected" LED along with a resetable timer. You are talking maybe $30 worth of parts!

Note that you will need to test its susceptability to other RF in the area so it doesnt give false readings.

One assumes you want to log the above events? For that a PC can be used for with a simple low rate data acquisition module or even via the parallel port pins. As horrible as it sounds using an old clunker and a DOS version with debug will allow you to poll the printer port and print a report on completion. You can also do it with the normal tools in a current Linux versions. I think software would need to be written for a Windows environment. Probably already exists as GPL. Shd be pretty simple to write though if not.

The above assumes you dont need to measure the actual exposure level..

You might be interested to know that back in the early 1980's I was involved in medical ultrasound. Most of our products were for imaging and doppler. We were however developing a higher energy device for focussed heating on cancerous etc areas. The initial tests were done with a beefed up transducer (about 50mm dia a 5mm thick) in a water bath and excited with an old Yaesu FT101B transceiver on about 3.6MHz! It was impressive to watch it boiling the surface of the water. It looked like a 360 degree waterfall..

If you want to go down the separate radio and PC device have a look at the Winradio (or similar) boxes. They use a PC as control and display for an external box with an RS232 and antenna port on it. Dont know about the software side of this though.

In theory, with a perfectly flat perfectly conducting infinite plane --
yes. In practice -- probably. You could spend a bunch of time messing
with EzNEC or other antenna modeling software, or you could just give
this a try.
>
> 2. Would the 17" square hole that the antenna sticks out in the belly of

Oh yes. If possible you should make the antenna's ground plane
electrically contiguous with the skin of the heli, which should itself
be electrically contiguous -- I'm not sure if you can count on that
being the case.

> 3. For maximum gain, what needs to be grounded to the helicopter if
> anything: non radiating elements, the receiver, etc.?

All of above. For this to work in theory you need to have the center of
each element well grounded to your ground plane.
>

In general elements need to get shorter as they get fatter, and the
bandwidth goes up.
>

>
Dunno, Google on "Yagi". If it were me I'd get a copy of the ARRL
Handbook or antenna book, copy a compact 2m yagi from that and scale it
as appropriate for the new wavelength.

Tech support at BuxComm emailed me back, and the antenna is indeed
not an OCF. It is an equal leg length antenna. My deduction was incorrect.

What an odd antenna! I was referred to a similar antenna in the ARRL
handbook, although I'll note that it used ladder line instead of a balun
and coax.

The response was very prompt and courteous, and although I could see
myself buying some of their other antennas, I think I'll pass on that
one! 8^)

Robert, I think I would get my hands on another militart type
(aerodynamic) vhf aircraft antenna and then have my aircraft
electronics shop cut it down for your frequence and then install it.

You know from your air-to-ground VHF communications what to expect
from it. I don't think you can do much better than that. Over water,
at any altitude above a few hundred feet MSL, I would think it would
cover your area of interest.

74. Re: Creating dual band HF antennas using a loading coils.

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-03 17:28:05 UTC
From: John Passaneau <w3jxp@adelphia.net>
Message-ID: <0NudnW-tK-07zjTZnZ2dnUVZ_tGdnZ2d@adelphia.com>
Source record: 56761

My antenna for 160/80/40/30 is as follows:

160m loaded dipole shortened to 200' with 30uHy inductors so it will fit in
the lot.
80/40 parallel fan full size dipoles at right angles to 160m dipole
30m the loading coils on the 160m dipole act as RFC's or traps on 30m to
isolate the center section of the dipole as a full size dipole on 30m.
All with a common feed point through a home brew 1:1 current balun.

I was modeling the whole array before moving the loading coils in EZNEC and
noticed that I had a near perfect resonate point at about 6MHz defined by
the loading coils on the shortened 160m dipoles center loading coils. As
this is in a shortwave broadcast band it was hitting the front end of my
radio with very strong signals. As I'm a DXer I didn't like the idea that
strong out of band signals may have been degrading my in band receive
performance. The idea of moving the coils in to make a 30m dipole came to
me as a good way to fix the problem and give me a antenna on a band I had no
antenna for. To keep the length of the 160 dipole at 200' when moving the
loading coils in to make 30m dipole required increasing the inductance to
30uHy's. The SWR is a reasonable 1.2:1 and seems to work quite well. As 160
and 30m are the only bands I don't have DXCC on, I'm making good progress on
30m to getting it, not so good on 160m as I don't have an amplifier on
160m.

75. Re: Resonant Stub Measurement

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-03 18:14:56 UTC
From: Chuck Olson <chuckolson01@REMOVETHIScomcast.net>
Message-ID: <sMGdnbLDrrhTwzTZnZ2dnUVZ_qmdnZ2d@comcast.com>
Source record: 56762

I made some comparison measurements between various twinlead types after experiencing some difficulty in obtaining a 1:1 SWR in a Slim Jim 2M J-Pole using Channel Master 9354 Vinyl / Polyfoam 300-ohm cable I bought at Fry's. The enhancement/absorption disturbance of the coupled signal (see previous post, below) by the 1/4-wave
stub measured 6.7 dB with the CM cable, while some old Belden 8225 ribbon-type 300-ohm cable showed an 11.6 dB peak to valley measurement and 450-ohm ladder line using 18 ga solid conductors displayed a huge 35.8 dB effect. I believe the magnitude of the phenomenon is partly related to the Q of the resonant stub, and in turn to its ability to reach a high enough impedance at the open end to match the end impedance of the 1/2-wave radiator. And of course, surrounding the stub with PVC tubing reduces the effect a bit, so that the CM cable peak-to-valley measurement goes to 6.0 dB.

I found fair success in wrapping the Belden 8225 stub section with some 1/8" thick foam sheet one can buy from a packing and shipping store to stabilize the effect of PVC tubing on the Velocity Factor of this cable. I cut a 1.5" wide strip from a 24" wide foam sheet and fastened the wrap with Mylar tape every 2.5" above the feed tap to keep the conductors spaced away from the PVC
wall. My final design had a 16.53" stub, 38.65" radiator, Feed tap at 1.75" and gap of 0.25", resulting in a 1.0 SWR at 145.48 MHz with R = 53 and X = 2 on the MFJ-269 Analyzer, and a 2:1 SWR bandwidth of 7.16 MHz (141.80 to 148.96 MHz).

The best SWR I could get with the Channel Master 9354, using a similar foam wrap inside the PVC was 1.3 at 145.98 MHz. This design had a 16.375" stub, 37.88" radiator, 1.625 feed tap and 0.375 gap. Its 2:1 SWR bandwidth was 5.08 MHz (143.72 to 148.80 MHz). Of course both Slim Jim J-Poles will work well when
applied at a suitable height, so don't lament too deeply the scarcity of Belden twinlead - - but if you see any at a swapmeet, it might be worthwhile to replenish your supply.

Pretty much line of sight is the rule at VHF and above. The line of sight is baaed on the curvature of the earth, and modified by the respective heights of the two stations.

A nice little on-line calculator is at:

http://www.qsl.net/kd4sai/distance.html

enter the heights of the two antennas, and it will calculate the distance that you can expect to cover.

Sometimes there are propagation effects that will dramatically extend the range, but these are the exception not the rule, and although amateurs have a lot of fun with the effect, it isn't reliable for any length of time.

>
>

Actually, if you check the ARRL antenna handbook or the annual
handbook, or maybe even the web site, they have a dual band 80/40
meter dipole that uses loading coils instead of traps. One version
uses a drop wire at the end of the 40 meter band to trim without
moving the coils or adjusting the 80 meter frequency.

I haven't tried it, but I have seen other antennas designed on it's
principal, mainly vertical 1/4 wave antennas, but they worked so I see
no reason the dipole shouldn't.

Will the fan-dual-band dipole work? I suspect so. However, I highly
suspect that the parallel dipole (a fan with the elements 6-8 inches
below each other) will work better.

Good luck
Buck

Yep...and tropo scatter, the only RELIABLE long-haul VHF mode is way too weak for TV broadcasting, though it does work great on CW or SSB with good antennas and equipment. When I had a 19el antenna at 85 feet in Nova Scotia, I could reliably work Cape Cod, 500 miles away, on 2m CW. But it took high selectivity, and a good preamp even with that antenna and both stations running about 600 watts out. About 60db overall path gain over a 1w signal. Plus the bandwidth gain from TV to CW is about an additional 48db.

Yes, but the trap (which is a parallel tuned circuit) doesn't need to
be resonant in one of the operating bands, and there are reasons for
choosing resonance other than at an operating frequency. For example,
you can design a 40/80 trapped antenna that uses a trap resonant
around 6MHz.

Such a configuration requires a bit more complex explanation than the
trap "cutting off" part of the antenna (which it doesn't do anyway).

I suppose someone that didn't have a PC available to run DXATLAS might
want a wall map. For myself, wall space is at a premium, so anything
that I can do with the PC is better for me than a wall map.

DxAtlas (available shareware at dxatlas.com, $29.95 registration after
some preview time) provides a wealth of information relative to what you
are describing. Not only can you set it for your QTH and display the
world as a map, you can click on a given location and it will give you
the bearing heading and distance! It also integrates well with other
packages such as IonoProbe, and a large group of other programs...
All much more useful than a wall map, in my estimation...

Thanks

I believe that the W3DZZ antenna uses this principle to get a reasonable
match on several bands with only one pair of "traps".

=====================================

Use program NOTATRAP. The parallel tuned circuit is not a trap at
either of the operating frequencies. Its resonant frequency lies in
between the two operating frequencies. The two operating frequencies
do not necessarily have to be harmonically related.

All of his measurements are seriously lacking substance. I wouldn't
trust them.

To answer your question, there is NOTHING that indicates his method
improves performance, and a great deal that indicates it is far from an
optimum system.

What do they mean "calculates"??? That's a very odd word, because it implies they never MEASURED the reference antenna. Also no one states what the reference antenna was, other than a "perfect monopole over perfect groundplane". IF it was perfect, that means it was not a real antrenna. If it was not a real antenna, we are at the mercy of calculations. I can assure you that is NOT how an antenna test is done on a test range.

It is also impossible for a significantly shorter antenna to have gain over a perfect monopole over perfect ground when the antenna under test uses a real ground and real antenna losses.

In my opinion, the press releases are all bullcrap.

Since the 1920's it has been well established a 1/8th wave tall monopole has about the same FS as a full size antenna when over a very good ground system.

Big deal.

There is a small advantage. The whole length of the antenna is used
at both frequencies. Furthermore, the antenna can be used multi-band
at frequencies higher than the lowest design frequency. Including the
frequency at which the trap is resonant if it lies in an amateur band.

But there will be some peculiar drive-point impedances presented to
the transmission line plus tuner. For multiband use one might just as
well remove the trap which is not a trap and use the antenna simply as
a random length wire.

hello,

50 ohm is the standard port impedance.for 2.4GHz and an Fr4 substrate of say 4.2 dielectric constant and 1.6mm height, the computed/simulated Zo from ADS2004a line calc, is equivalent to about 3.12mm. also, for traces less than 1/20 of the guided wavelength, matching is not necessary.

the question is this, most of the RFIC's or SOC's usually employ RF feedlines at 2.4GHz lower than the 3.12 mm computed. for one, a Sige 2.4GHz amplifier RFin and RFout port is about .62 mm and the fact that the trace extends greater than 1/20 or 1/10 of the guided wavelength...or is it because they used a different substrate of higher dielectric???

thanks

Hard to rely on the RX end of broadcast to put up sufficient antennas
to hear troposcatter signals...

Maybe with lots and lots of power on the TX end and a robust digital
mode you could do troposcatter broadcasting to the general public, but
it's a lot easier for point to point links..

Well the exact answer to the exact question is: As far away as they can be!!
[I'm in New Hampshire and I'm sure somewhere in Europe VHF signals are being
transmitted. But, I surely can't hear them :-)

Allowing for the ambiguous wording and hopefully moving to the intent of the
question A 1000 feet high tower will have about a 50 mile radius range.

A 2000 feet high tower will have about a 70 mile range.

a 200 feet high tower will have about a 20 mile range.

Hi Electro, If you are posing these questions to a Ham Radio
Newsgroup, then you need to explain what an ADS2004a, RFIC, and SOC is
related to the 2.4GHZ band. I have been a Ham for 45 years and never
heard of this stuff. There may be a Ham band around 2.4 GHZ, but for
me 70cm is the highest. Maybe some microwave guys will give you some
answers. Good Luck.

I'm guessing you are asking about "DX" or "DX'ing," the art, science and hobby of long-distance communications. One good TV DX website is http://www.w9wi.com/.

1000 miles is unlikely but not impossible. 100 miles is quite reasonable I am 124 miles south of Mt Wilson, the transmitter site for Los Angeles TV, and I get them more or less reliably with antennas about 30 feet above ground. At that distance, the problem is not signal strength, but it is being behind the "bump" caused by the curvature of the earth. Mt. Wilson does me a big favor by being about a mile high.

Some years ago in Norfolk, Virginia, I watched a late-night movie from a station in Buffalo NY, over 400 miles away. The picture was snowy, but good enough to permit enjoying the movie. That was a rarity, as most nights after that I saw little or nothing of that station.

The best TV DX I have ever had was one night in the winter (Jan. or Feb.) back about 1992. I was living in far Northern Wisconsin and I got the news from a New Orleans TV station (Ch. 3 I believe) and the video was very good with full sound. I had the TV running in the other room and didn't even suspect that it was not my normal channel out of Duluth, MN until the weather forecast came on and said the high temp expected was going to be in the low 80s (that would be VERY unusual Wisconsin weather for the middle of winter)!!

I looked at their web site and did not see a 'Log Periodic'.

Their antennas seem to be Yagi based. A L-P is a driven array, not parasitic, and broad banded so that the VSWR never exceeds a max value, typically 1.7:1, ANYWHERE in the spectrum from 14 to 30 MHz in the bandwidth you mentioned.

Do you have a model number?

Additional info re: Log Periodics.

Typical VSWR values for a 13 to 30 MHz LP are as follows:

13.5 MHz ... 1.7:1
13.7 MHz ... 1.6:1
13.9 MHz ... 1.4:1
14.1 MHz ... 1.3:1
14.3 MHz ... 1.4:1
14.5 MHz ... 1.5:1
14.7 MHz ... 1.7:1
14.9 MHz ... 1.7:1
15.1 MHz ... 1.6:1
15.3 MHz ... 1.5:1
15.5 MHz ... 1.4:1
15.7 MHz ... 1.3:1
15.9 MHz ... 1.3:1
16.1 MHz ... 1.4:1 ... continuing through 30 MHz for a 13 to 30 MHz antenna.

Note: On 10 meters my VSWR does not exceed 1.4:1 anywhere from 28.0 to 29.7 MHz.
I don't believe a Yagi design is that broadbanded.

The VSWR on my LP does not exceed 1.7:1 anyplace between 13.5 and 31 MHz. It
varies slightly between 1.7:1 and 1.3:1 minimum.

Gain is effectively constant between 13 and 30 MHz. However, it is slightly
lower than a well designed 3 element Yagi. [~-0.5 dB]
Efficiency, however, is slightly better than a trapped Yagi [no trap losses].
Physical size is larger than a trapped Yagi.
F/B ratio on 14 MHz is lower than a Yagi but will match a yagi on 18 through 30 MHz.

I chose a LP because I wanted full coverage of the HF spectrum from 13 to 30
MHz. [Including USAF MARS & 17 and 12 meters] A 5 band Yagi only covers 5

segments of that spectrum.

If I were interested in one or two bands only, I would go to a full sized 4 or 5 element Yagi for for each band and get excellent gain, efficiency and F/B. [Assuming I had the $$$$]

Gander Mountain is a nation wide outdoor sporting good store. They are currently selling a 20 foot collapsable Crappie pole that is perfect for playing with verticals.

It's the Creekside Brand Model CST-20, it's a six section fiberglass collapsable pole that is being sold for $12.99 in central Indiana. It's a little bit more rigid than the SD20 (I have some of each).

Heads up on a good buy!

Dave,

Thanks for your comments, the Optibeam antenna model I was looking at is the OB9-5 broadband antenna. The spec's seem good, low wind load and looks like it would survive in the sunny south were we do get those darn Hurricanes. I live in Central Floria. My TA-33 has gone through 4 storms with some very gusts of over 100 MPH and still preforms without a change from the day I put it up back in 1988, almost 18 years, thats service.

The other antennas I am looking at is the Summer XP504-6 LP that is rated 13-54 MHz and the Cushcraft ASL2010. The gain figures look higher than the Optibeam but I guess that its all relative.

Theres no doubt that the SteppIR 3- element is a great beam, but from what I have read over the past few years since it first hit the market is that there has been problems, both mechanical and electrical. That fact frightens me, here I live in the lighting capital of the world and also from time to time need to adjust to Hurricanes, if I didn't love golf also I probably live future up north in SC or NC but thats not the issue. In a few years my days climbing towers will get very difficult

and probable not to smart.

After looking at the choices one has in a multi-band antenna for 20-6 meters I have come to realize that the LP maybe my alternative for a long term survivable antenna. You were right after looking at the Optibeam it is not a LP like the Summer or Cushcraft.

What bothers me about the current LP offering is I do not see many opinions or comments relative to this type of antenna, guess everyone likes the new SteppIR and before its over I may re-think my choices.

Again thanks for the comment

Ok you antenna gurus, I have a funny problem. Whenever I try to reach a certain repeater on 2 meters, (146.700-), I can't do it. The repeater is about 25 miles from here. I have an outside antenna with 6 db of gain similar to a Diamond, a new coax and 50 watts of power. The base of the antenna is about 15 feet fron the ground and the repeater doesn't need a tone. What's funny is that I can reach repeaters that are a lot farther than this one but not on the the same bearing. A friend of mine who lives about 3 miles from here has no problem whatsoever in reaching the same repeater. Some hams who live farther from the repeater than me can use it with no problem. The only difference I can spot is that there are a few houses around mine that are 4 stories high while mine is a bungalow. Could this be the reason or am I missing something here? Thanks for any help.

From the antenna, I can't see the repeater because of a couple of condos that are much higher than my house. That's probably the problem because I can reach a few repeaters about 4 times farther but not in the same direction. I wonder how high my antenna should be to solve my problem. I also wonder if more power, say 150 watts would change anything. I am open to suggestions.

The Only problem with the Optibeam is that their gain figures are
honest! I think if you look at Cebiks web page a at his Log periodic
models you also see how good LPDA's can be.

What makes both the LPDA and the Optibeam look bad is the exagerated
gain claims from old antennas designs. We see LPDA's get tarred with
this brush daily, yet we know any decent lpda will just about perform
as well as any mutiband tribander.

Whats amusing is that you see people time and time say that a 5 element
monoband will beat a 32 foot lpda by several S units. Yet we know that
a decent LPDA of this boom length will have a gain of about 8dbi versus
a monoband antennas gain of 10dbi! So you tell me where even 1 s units
gain comes from?

What does not help the logs case is the dishonest manufacturers who blow
up their gain figures. People like Tennadyne, who seem to mix up dbi
with DBd.

If it was my money and i wanted a small multiband beam antenna i would
buy the Optibeam, because 2 or 3 dbi does not mount to much on HF. I
would rather go for all band coverage with reliability versus something
like a Steppir which still is unproven.

Optibeam have a nice model that covers from 40 through to 10 even 30
meters. Now if you looked at the same size log needed to achieve that
with similar gain you see what a good design it is for ham radio. I
dont buy all the crap spun by Optibeams owner about LPDA;s and harmonics
etc. Harmonic suppression is a transmitter problem should never be the
antennas problem. If you have a receiver that cant handle a log because
of 2nd order IMD issues you have a crap receiver.

Whats also interesting is that if you model a stack of LPDAs like N08D
has which is six logs on a 200 ft tower you see the gain is just about
equivalent to a monoband stack, and this is from 13 to 30 mhz. There is
some guy in W1 land who runs 2 big logs on a 100ft tower, if you heard
his signal from a distance you would be impressed.

But dont worry too much about gain in any decent multiband beams like the steppir and the optibeam. I beat stations with a 4 element steppir's antennas with a high double extended zepp antenna. I would rather have a low gain LPDA up at a 100 ft than a Steppir down on a 30ft pole. In fact a lazy H at a decent height would perform just as well as most small tribanders or a small 2 element cubical quad.

You dont have to take mine or anyones word for it, just look at the reliable models on Cebiks web page. You soon see that most of the gain claims by optibeam. Force 12 is another company that has decent honest figures.

You may be running into a multipath-nulling problem.

I had a similar situation here at my house a few months ago. One of
the local repeaters is located about 5 miles away, with its antenna on
top of a 7-story hospital building. My antenna is a copper-pipe
J-pole, about 20' off of the ground (8' above a 12' roof).

There is an industrial/office building about 50' high, smack-dab
between me and the repeater. It's located around 100' from my antenna.

I found myself unable to open the repeater and get acceptable quieting
even with 50 watts of power. Another local repeater (further away)
gives me an S9+10 reading or better with only 5 watts.

I wandered around on my roof with an HT and a rubbber duck, while
another local ham transmitted through the repeater. I found that
there were places in which my HT received a perfectly good signal from
the repeater, and others where it dropped down pretty far into the
noise.

What I concluded was that my signal path to the repeater was really
messy. There was no direct line of sight, but multiple indirect
paths... knife-edge diffraction from the top of the office building,
with reflections off of numerous nearby trees and houses. By chance,
I had placed my J-pole in a spot where the various indirect-signal
paths summed up to a deep null on the repeater input frequency. When
I transmitted, the power ended up going in many directions, but none
ended up at the repeater :-(

I moved the antenna mast a few feet along the house wall and tried
again... and opened the repeater with acceptable quieting with only 10
watts. Problem solved.

So, I'd say that the brute-force way for you to solve your problem is
to raise your antenna until it clears the roofline of the condos and
has a direct line-of-sight to the repeater. If you do that, you can
probably open that repeater acceptably with only 5 - 10 watts even

using an omnidirectional vertical antenna - less if you aim a gain antenna towards the repeater.

The subtle way, not requiring a huge mast, is for you to experiment with moving the antenna around, both from side to side and in the direction towards which it's pointing. You may find that moving it places it in a spot where the reflections and diffractions work in your favor (waveform reinforcement) rather than against you (cancellation). You may also find that pointing it _away_ from the repeater, towards some tall building or hill which is located in the line of site of the repeater, will give you an acceptable (albeit indirect) path.

You can do some of this testing by simply listening to the repeater while other people are using it, but the fine-tuning will probably requiring transmitting - the cancellation and reinforcement path "sweet spots" can be different in the two directions, due to the different wavelengths of the repeater input and output signals.

113. Voltage feeding a VHF yagi

Newsgroup: rec.radio.amateur.antenna

Anyone ever get around the VHF FM vertical yagi feedline routing problem by voltage feeding the bottom of the driven element with a stub like a J-pole? A quick EZNEC run seems to indicate that it's not a bad idea.

So it seems like it might work OK... but I wonder if anyone has actually done it. Would you expect a coaxial stub to work better than a parallel wire stub in terms of preserving the pattern of the yagi?

Any commercial products doing this?

I do recall seeing one design for a "Jagi" - a three-element vertical
beam in which all three elements were of the copper-pipe J-pole style
of construction. It was reported to work pretty well. I'm afraid I
no longer have a reference to the design... sorry.

>So it seems like it might work OK... but I wonder if anyone has
>actually done it. Would you expect a coaxial stub to work better than
>a parallel wire stub in terms of preserving the pattern of the yagi?

My guess is that either could work. For the parallel-wire/pipe stub,
it might be best to use the time-honored trick of making a half-wave
coaxial balun, attaching it a bit higher than you'd do for a direct
coax attachment, and insulate the bottom of the stub from its mast.
Adding a ferrite or coiled-coax choke to the feedline might also be a
good idea.

I guess I'm missing it, but what problem is there
running the feedline to the normal center fed yagi?
No matter if against a mast, or mounted on a mast
with the center of the boom attached to the mast, I
don't see a problem. I do it all the time.
No matter what polarization, I tape the coax to
the mast, and then tape it to the boom to the feedpoint.
I'd much rather run the yagi in the normal manner.
Trying to voltage feed one sounds like a common
mode nightmare , unless drastic precautions were
taken. And I probably don't have to mention how
radiation from a feedline can skew a antenna pattern
real nicely... :(

Have you actually tried simulating the coax or a pole going through the yagi? You might be surprised at the results. The effects are not as bad as you might at first think. You should be able to optimize the positioning of the coax. For example, my simulation of an 8 ele vertically polarized yagi shows less than half a dB loss in gain with a 2" dia pole through the middle of it, if carefully positioned. It is possible to reduce the loss even further but it would mean putting the pole in positions that you would not really want to. There ate some effects on the f/b and side lobes but nothing too detrimental.

This is a problem that is particular to vertically polarized yagis that are mounted with a pole going between the elements. The pole has to come up parallel to the elements to the boom. Some people overcome this by using non-conductive pole, BUT what do you do with the feeder, if you tape it to the pole you might just as well have used a metal pole!!!

However, as I said in my previous post, my simulations seem to show that with careful positioning the effects can to quite small

Why would you want to take a directional antenna and feed it with one
of the poorest feed systems possible?

J poles and Zepps have terrible problems with common mode feeder
current because the feedline has an UNbalanced antenna element fed by a
BALanced stub that is fed by an UNbalanced coaxial line.

If you are worried about getting the feedline down an insulated mast,
offset the yagi out 5 feet or so on a cross arm or decouple the feeder
with a self- resonant choke. You could also use a sleeve or skirt
decoupled dipole. Any of these would be at least as good as an
end-feed, and more likely and easier to make much better.

I forgot to say you could offset the coax with a crossarm out from an insulated mast, not offset the Yagi. With a metal mast you would offset the Yagi.

It could be at the repeater, or it could be at your end.

Can you HEAR the repeater? If so, how well?

>with careful positioning the effects can to quite small

This problem has been investigated very carefully by moonbouncers who want to use selectable horizontal/vertical polarization.

The best solution from the electrical viewpoint is to mount the yagi on a fibreglass mast and route the feedlines out the rear, but this is not mechanically practical for very large steerable arrays. Simulations have found that metal masts in the plane of the elements can be used, and feedlines can follow the same route, if - BUT ONLY IF - the yagi is suitable and it's done at the right place along the boom. Under these conditions, the penalty (in terms of forward gain) can be less than 1dB.

However, only certain yagi designs will be suitable, because the support point must also be close to the mechanical centre of gravity. These electrical and mechanical requirements may conflict, so I strongly agree with Jeff that the effect of the mast and feedline will always need to be simulated and computer-optimized. There is no way to guess at this one.

Coming back to the original question about a J-pole feed for a vertically polarized yagi, this technique was used in the 1950s-60s by the British company J-Beam for TV antennas around 50MHz. The driven elements that I remember were not actually J-shaped, but used a coaxial decoupling sleeve that also served as a mast. The bottom end of the sleeve was typically clamped to a chimney.

It worked... but in those days, nobody really understood how well or poorly it worked.

Bob Bob, you are outstanding! The Winradio is actually a capable and
affordable solution. From the specs, it looks like it will fit the
bill, and the fact that they have a Linux version is great. Take care.

I can hear the repeater very well, in fact, it comes in at S9+ all the time.
I noticed that my SWR is around 2.5, I wonder what can cause this.

Can the repeater reach _you_? If not, no amount of power will help you
receive it. If you're almost making it then yes, more power may make a
difference. You're only talking about a 3dB increase from 50W to 150W,
though, I'd expect that if it helps at all it'll just get you to the
stage where you're cutting in and out instead of not hitting the thing
at all.

How high is the terrain where you live? I'd expect 2 meters to get
through (or around) a condo OK, but a hill between you and there would
certainly kill the signal. If the condos weren't there would you be
able to see the repeater?

Verify that you are really dialed into the proper frequency. It is
very easy to select the wrong offset or plus/minus 5khz.

The high swr is likely causing the transmitter to "safety" itself by
reducing power. Verify that this coax is in fact connected and that it
is not shorted somewhere. It sounds a lot like what happens when I
plug the wrong coax into my transmitter!

Coax problems usually happen at the connectors.

I think you mean a ~5dB increase, Tim (pedant mode off) but with an FM
repeater a few dB can make a huge difference.

The problem with many models is people just stick a source at the
feedpoint and assume it tells them something about how the antenna
works in the real world.

A model has a PERFECT source that is like using a perfect balun and a
transparent feedline. I can build a very feedline critical antenna with
horrible balance issues, one that will never work in the real world,
and make it behave quite well in the model.

I would never use a J-pole feed on a Yagi, except perhaps in a model.

If the repeater is S9+ on your receiver, unless the repeater is runing very
high power (300 watts +)
you should be able to hit it with a few watts. Sounds as if you need to
take your rig to another place and see if you can hit the repeater at all.
Maybe the repeater needs a subaudio tone to activate it and you do not have
it programmed in ?
You did not say what kind or how much coax you have between the rig and the
antenna. A SWR of 2.5 seems way too much. If you had about 100 feet (30
meters) of rg-8 and a very bad antenna, the swr would not be too much
higher.

Anyone here tried an HF horizonal loop built around residence? (either attached under eaves or to trees very close by)...
Did it work? Affects of antenna on residence electronics and vice versa?
(100 watt TX)
Would plan to use on several bands w/antenna tuner & open wire feed.
Tnx for comments...

Thanks for the responses.

Tom, I didn't know that the feedline decoupling issues with J-poles were so bad.

I'd be interested in more information about why it's such an issue. Would a sleeve stub work better than an open wire stub? It's certainly stupid to make the feedline MORE of an issue.

I like the sleeve/skirt decoupled dipole idea.

I hadn't thought about routing the feedline out on a sidearm. I was thinking of doing that with the antenna, but with a large yagi it would be a problem. Putting the feedline out a few feet and then dropping it down to a lower point on the mast could certainly work.

As far as putting the feedline in the plane of the elements, understood on the modeling and placement issues.

If one were to do this, would it help to have ferrite beads all along the coax from the feedpoint to some distance down the mast? Of course good feedline decoupling is important for any directional array, but I imagine that a wire with a string of ferrite beads on it is pretty much invisible to RF... is this right?

Maybe a long bead balun dropping away in between elements would be a good way to go with no sidearms?

Thanks for the responses; I'd be interested in further ones.

Newman,

I did that at a condo which I was renting. With a simple antenna tuner, using a choke balun, it loaded up fine, and more importantly got out well enough to work plenty of people, including some DX.

I got some rf into an answering machine, as well as my TV. Both of those were the result of the phone line and the OTA TV antenna having to pass near the loop. No problem with the neighbors.

Such an installation depends on a host of factors specific to the QTH, as well as basic antenna factors. Things like metal siding, gutters, especially with poor joins between sections, wiring and copper plumbing in the wall, etc, will all have effects on the questions you asked. Best advice is to give it a try. Not much cost, and you will probably get good results.

I am currently using a HF loop = 180 feet is laying on my roof and the remaining 360 feet is in the attic, I drive it with a 706 @ 100w and a MFJ tuner, and RG8x coax to a center feed point - works very good from 160m to 6m and becomes a rhombic of sorts from 220 MHz to 440 Mhz.

I had an 80M loop up for a while. Put a mast on each end of the house & used some trees in the back yard. It was kind of a lop-sided pentagon and up about 25' or so. I fed it 100W with ladder line & a Johnson Matchbox. I was very happy with it. It was a bit of a cloud-warmer on 80 but did pretty well on the upper bands. I regularly used it on 20M for a sked with a buddy in Indiana (from Arizona). A storm blew down a couple of the trees or I'd probably still have it. I don't recall any RFI in my house altho my neighbor had a problem with one of his el-cheapo phones. If you have the supports, go for it...it's only a couple hundred feet of wire and you might be surprised how well it works...

137. AM-FM broadcast radio/antenna in truck?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-07 00:15:31 UTC
From: "carkenord@juno.com" <carkenord@juno.com>
Message-ID: <1152231331.422720.307440@s16g2000cws.googlegroups.com>
Source record: 56824

I have an external vertical antenna on my 2001 Ford F-250 pickup.
It's OEM, for the AM-FM broadcast radio in the cab of the truck.
This is a metal antenna, tapered from base to tip.

This antenna is about 32 inches long, and sticks straight up in the
air. It appears to have something spirally wrapped on the exterior of
it, helically wound, with about 1 turn per inch of antenna length.

Does this antenna serve both AM and FM? I can't tell for sure, but
it looks as though there is coax running from the radio to the base of
the antenna. No markings on the coax that I can discern, but it hard
to see up under the dash, with a flashlight!

What would be a probable ohmic value for this coax, if indeed that
black cable IS coax!? Would it most likely be approx. 50 ohm.....or
75 ohm.....or what?

What is the likely (or "common") configuration of the above
antenna? Would I call it a ¼ wave vertical for the FM freqs? As you
can tell.....I don't know much about how an AM-FM auto radio and
antenna are designed.

Any chance that the AM part of the radio uses a ferrite rod antenna,
and that the external, visible antenna is FM only?

This radio is a VERY good receiver, compared to 3 other AM-FM receivers
that I have.....Sony, GE, and a Grundig. It "pulls in" weak
stations in an impressive manner.

Please, someone fill me in a bit here, or direct me to a good website.
I _HAVE_ GOOGLED around, but found mostly nothing pertinent to my
questions.

Thank you so much..... Lee Carkenord

138. --W8ji-- Faraday shield

Newsgroup: rec.radio.amateur.antenna

Hi Tom,
I'm winding some Flag antenna transformers and measuring
capacitance between pri. and sec.

A one point somewhere you said ;
" The proper grounding point for a Faraday shielded primary
is opposite the exit point of the primary winding, or on the
secondary winding's exit side of the transformer. Most Faraday
shields described for Beverages and other transformers are
not only useless, they are often incorrectly grounded and
actually increase unwanted coupling!"

Sorry if this out of context, I'm just trying to get info.

Btw. I'd like to apply any response to potcore transformers.

Is the exit point you mention related to the impedance of the winding?
Do I want to exit with the lower impedance winding?
If I use a Faraday shield, the grounding wire is a 15ft horizontal run
and a 20ft vertical drop, before earth ground. Is it still reasonable to
think it will work?
Mike

> Would a sleeve stub work better than an open wire stub? It's certainly
> stupid to make the feedline MORE of an issue.

Look at what the J-pole really is.

1.) You have a half-wave end-fed antenna. There has to be as much common mode current leaving the end of that point and flowing down the feedline as there is flowing out onto the antenna at that point. There isn't any exception to this rule.

2.) While that current may be small with a perfect half wave, it is never zero. It gets worse fast of the antenna is not 1/2 wl long electrically, or if it is thick.

3.) Now you have a 1/4 wl stub feeding that half-wave on the end. If you perfectly floated that 1/4 wl stub, common mode current in the stub would DECREASE as you move away from the feedpoint. But if you ground the 1/4 wl stub, current common mode INCREASES as you move away from the stub. This is why end-fed Zepps and J-poles model very good when a perfect ground independent current source is used to feed them. Unfortunately we can't do a perfect ground independent feedpoint in the real world, so depending on the CM impedance the amount of pattern distortion will be all over the place.

This is why Zepps, antennas that are really just the same as a J-pole, are notorious for RF in the shack. The lack of feedlines in models are why people who do not include the feeder or feedline matching device to the 1/4 wl closed stub conclude they aren't so bad.

Why would anyone go through all that bother to complicate the feed system in a Yagi is beyond me, when there are a half dozen easy solutions that were mentioned here.

I added a "flying winding" to balance the seconday capacitance to
ground, not to reduce it or shield it.

> Do I want to exit with the lower impedance winding?

I'm not sure what you mean. What I did won't work in other
configurations.

> If I use a Faraday shield, the grounding wire is a 15ft horizontal run
> and a 20ft vertical drop, before earth ground. Is it still reasonable to
> think it will work?

No. The "faraday shield" will likely just couple signals and noise from
the ground lead right into the antenna. I'd avoid the whole thing, and
just separate the windings as much as losses allow. Hopefully you are
using small low capacitance windings.

In fact, I found out that I can hit the repeater sometimes if I let the carrier run for at least 5 seconds. I did reach it this afternoon every time I tried but can't reach it tonight. It is as if not enough power is reaching the repeater, probably because of distortion caused by the large condos in the path, that would explain the long time needed for the repeater to react to my signal. The antenna I am using is a Quantum QT-6A dual band with 6 db of gain on 2 meters. My coax is 60 feet of RG-8X mini foam (I think this is too small) and the radio is a Kenwood TM-G707A with 50 watts out on 2 meters. The repeater does not use a tone and is on a mountain at a height of about 1000 feet, it is 24.5 miles from here and I am 60 feet above sea level. The SWR was measured with a meter that is supposed to be unreliable on 2 meters so I don't trust the reading, anyway, my radio seems to find the antenna acceptable. The thing that proves that my setup is working right is that I can reach a couple of repeaters that are more than 70 miles from here but not on the same heading as the problematic one. I think I will get my antenna higher and maybe move it a few feet from where it is. Thanks for your help and suggestions guys, it is much appreciated.

VE2CJW, Mike.

It certainly isn't that simple in a distributed network.
The currents into the end of a half-wave section are certainly
unbalanced at X and Y but the current amplitudes are pretty low.
5 watts into 5000 ohms is only about 30 mA. 1/4WL back at the
shorted matching section at ++, the currents have to be close to
balanced because of the short. The coax connection at A and B is
closer to the short than it is to to X and Y. The current down
the coax braid at B does NOT have to be equal to the current at
the feedpoint at X since they are a good percentage of 1/4WL
different in location. And common-mode current can form standing
waves so common-mode current maximums and minimums exist depending
upon location on the feedline. The lumped circuit model strikes
(out) again.

While there antennas that are wrapped with wire, such as some shortened
CB antennas, most auto radio antennas that have this spiral appearance
are made that way to cut down on wind noise - it isn't wire.

I looked in some of my dusty old Optics texts to find Brewster: has
more to do with polarization. Brewster's angle is the incident angle of
light at which the reflected beam is the most completely polarized.

My bad.

I was thinking of the critical angle above which the light is reflected
back from the media interface and below which the light is refracted
through the "2nd" medium.

PseudoBrewster's Angle (PBA) is the "angle at which the reflected wave
is 90 degrees out of phase with respect to the direct wave" (p. 3-13
ARRL Antenna Book).

I see now that Both Brewster and PBA have to do with polarization.

If the end result is that the wave returns back to earth, why is this
not termed reflection? Even if it is the result of several and/or
continuous refractions that result in a return of the wave from the 2nd
medium to the 1st, i.e., they sum to result in a reflected angle, seems
to me reflection is a good term.

I understand that a curved surface is more complex but if the result is
the same, ...?

>> not be too much higher.

2.5 to 1 measured at the transceiver is an enormous SWR. If it were INFINITE at the antenna end, you'd still only get 3.2 to 1 or so at the end of 60 feet of RG8X. Replacing that coax with LMR400 or, better yet, heliax would, the problem is with the antenna, give you a much higher SWR.

The trick is to find some way to measure the SWR at the antenna. If it is atrociously high, then you have an antenna problem (something is broken or not connected properly). Measuring SWR at the transceiver on VHF is almost useles unless the coax run is very short or very low loss.

60 feet of RG8X will only transmit about 53 percent of your signal anyway. The rest goes to heating the coax. If the SWR at the transceiver end is 2.5, it's probably well over 10 at the antenna, which means you're probably not getting more than 1% of your folded back signal out into space.

If it was mine, I'd bring the antenna down and test it at ground level until I got it taking power properly. If you can borrow an analyzer, even an MFJ 259b and measure the antenna directly at its terminal, that will help you see what the antenna is doing.

I think the AM receiver input on car stereos is VERY VERY high
impedance; the antenna on AM is basically a voltage probe.

I don't know if the FM RX input is the same way, but the antenna is
just a stick of stainless steel.

The car stereo uses the single antenna for both bands as far as I
remember; a ferrite loop doesn't work in a car - - - you'd get fades
going around corners, etc. because of the directionality.

The spiral wrap is plastic. It does something to break up the vortices
that would usually be shed periodically off the antenna in the wind.

Dan

Anyone have experience with horizontal loops in a triangle shape?

I have trees on my property that will allow this configuration. I'll have about 100' on each of the three sides. It is pretty much an equilaterl triangle, and the height should be about 60 feet. I'd like opinions before I go to the effort of getting it up. I'd also like opinions on whether or not it should tune at all on 160M. I have an MFJ balanced tuner to feed the 600 ohm ladder line I plan on using.

Triangle will work fine.

160m probably not; it's a bit short. It would help if you included a
relay opposite the feedpoint to open it on 160m.

I've read of people using an L/C resonant trap instead of a relay, for
just this purpose. The trap opens the loop on the lowest band, and
appears as a capacitive reactance in series with the loop on the
higher-frequency bands.

<ve2cjw@videotron.ca.nospam> wrote:

>I can hear the repeater very well, in fact, it comes in at S9+ all the time.

Ok, finally, that is an important observation. Don't forget the S meters on FM radios are not usually calibrated to the popular S9=50uV, more like 10uV fsd. That aside, the repeater should be workable if you address the issues below. (You have indicated in another post that you can key it up with a long carrier burst, so that clears away access tone issues, however some repeaters may use the Motorola smart mute idea where the carrier squelch is set at a relatively higher level that that which will open the CTCSS.)

Over here, repeaters are not always balanced in terms of rx and tx, they are usually designed to be a little easier for mobiles to hear because of the higher noise environment, so it may under normal conditions hear you a little poorer than you hear it if you are running ~25W. Is that the practice in Canada?

>I noticed that my SWR is around 2.5, I wonder what can cause this.

Firstly, because of the inherently higher loss of coax (I assume coax) at 2m, you can not usually afford high VSWR on most practical coax runs. As an indication, most commercial antennas intended for 50 ohms coax connection would specify a max VSWR of 1.5 or less.

Secondly, the VSWR at the antenna end of the line is even higher, and you wouldn't normally be using an antenna that would exhibit such a high VSWR if it were operating properly, so it is a sign that the antenna / feedline system has a problem.

Thirdly, standing waves set up in space around your antenna as a result of the interference of waves arriving by different paths. A similar effect occurs on transmit. It is possible that your antenna is located in one of these nulls, and moving even slightly might make a large change. If that is happening you need to find a sweet spot that works for both transmit and receive on that frequency without messing up operation with other repeaters on other frequencies.

You could choose to play with the third issue, but your antenna / feedline has a problem that should be attended to as a priority, regardless of whether you trick your way into the repeater.

I think normally the effect is fairly small. But I suppose it can vary
per the position, and mast length, etc.. I guess it's all how picky
you are about the gain/pattern. For moonbounce, etc, it might be worth
worrying about. But for just a general purpose FM beam, I probably
wouldn't worry too much. Unless the mast was a certain length
to become resonant, it should pretty much be ignored by the antenna
for the most part. Seems to me, right in the middle of the two
midpoint elements would be about best, but I've never modeled
other positions. I have seen quite a few people run vertical yagis
with the midpoint mast mount with no serious problems.
I think any small loss of performance would be less than trying to
voltage
feed thats for sure. You'll see lots of antenna ad's with pictures of
vertical beams mounted on masts in that manner, so it shouldn't be
too bad. I agree. There should be little difference in using a metal
mast, or plastic, if the feedline shield is in place on both. I'd just
as
soon use the metal mast I think. It would look fatter with the extra
metal mast, but I don't know if that would be a plus or a minus...

If the VSWR at the tx end of your line is 2.5, it is likely to be
around 4 at the antenna if the line is in good condition. That antenna
cannot be designed to be such a bad match, so antenna and/or line have
a fault.

Of your 50 watts, less than half is reaching the antenna right now,
whereas if the antenna had a VSWR <1.5, you would get about 60% to the
antenna. Is that OK for you (antenna/feed faults aside)?

Do you use this on 70cm? The cable is even lossier with around 40% of
power reaching the antenna. You might be happy with that, it might
work the repeaters that you want.

That's interesting, Dave. Thanks. Will look into that as a relay would
be tricky given the location and height of my proposed loop.

Trap seems like a fine idea...

If it were not a multiband loop, I think you could use a relay with the coil in parallel with the contacts, so you could run DC on the feedline (if it were a dual bander of some sort) but the high voltages present on the open wire feeder would make it awfully hard to choke off the RF for whatever DC injection scheme you were using. I think you'd basically need a tuner with DC continuity, and the CLC tee that is so common in tuners isn't one.

I guess you need a big enough C on the higher bands to look like a short circuit in that trap if you want to have the loop appear to be a closed loop, but maybe that's not very important.

A relay inserted in an antenna wire can be operated via a pair of
wires (20 gauge twin speaker cable) which, in parallel, form the
single antenna wire.

At the shack end, DC power is fed into the pair of wires via an RF
choke. The choke consists of a pair of wires (more 20 gauge twin
speaker cable) wound on a ferrite rod.

Been there. Done that! I used a single-contact reed relay.

Hi Ed,

Your Loop is about the same as I'm using here it works great on 80-10m
But 160 is a bit of a stretch for it.. and I use an inv. L on that band
when I'm active there. But it's been a great loop here on the other
bands. You might try it first before adding relays and traps .. how
well it tunes will depend upon the range the tuner will handle. It
should give a good high angle lob on 160 and be good for local out to
say 500 or 1000 miles.

Since you are in Australia and you probably do not have a Yaesu repair
facility close by I would stay away from their crap radios.
Their VHF/UHF mobiles are known for poor performance, poor reliability and
just crappy built quality.
I have owned radios from all the major manufactures and Kenwood, along with
Icom are some of the best for the dollar.

A "Bullet-Proof" mobile for the money ($269 US) is the Kenwood TM-G707A.
Good performance all around.

TX Power doesn't solve everything...

If you can hear the repeater and it's in the same range of tx power that you use, you can reach it.

Your problem is probably an error in the subtone setting...

Have you checked if the repeater use a subtone?

If the tone settings and frequency shift etc, are correct. Take your rig to your mate and connect it to his antenna.

Cheers

==========
No arcing problem that I ever detected. Transmitter was 100 watts. I think the relay was rated at 750 volts and it may have been a vacuum type. Only used on the 160 and 80m bands.

It eventually failed because of intermittent contact on receive when no wetting current flowed. Perhaps it should have been mercury wetted.

That's a pretty husky reed relay but you are lucky
it didn't arc. Peak-to-peak across that relay was
higher than 750 volts if it was installed in a 1/2WL
dipole.

172. Reradiating RF signals from Satellital Modem

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-07 18:57:33 UTC
From: paggonzalez@gmail.com
Message-ID: <1152298653.803900.283720@s13g2000cwa.googlegroups.com>
Source record: 56709

I'm to install a satellital modem (Globalstar GSP-1620) in a place
where there's no full direct sky visibility due to some metallic
obstacules.
To overcome this problem I'm thinking of placing a reradiating antenna
or RF repeater over the top of the highest obstacule, facing the real
GSP1620 antenna down on the ground.

The GSP1620 has two RF frequencies, one for TX (1610-1625 Mhz) and
another for RX (2484-2499 Mhz). Does anyone have any ideas on how to
build up such reradiating antenna and/or RF repeater ? Is there any
commercial product similar to this ?

Thanks a lot.
Pablo

I've had no problems with MOST of my Yaesu stuff, having sold it on quite
soon after getting.

However I did buy a NEW Yaesu scanner about 5 years ago.

Back to dealer screwed up. NEW replacement supplied.
That went back to dealer screwed up. NEW replacement supplied.
This one sometimes throws a wobbly and needs a reset but at least it does
work (at the moment)

Never had a problem with Icom and their support here in UK is superb- email questions answered, copies of manuals supplied FREE for second hand equipment (when its not on their site). Can't fault 'em.

Source record: 56713

A simple E-field probe for measuring
near-field radiation (to verify
compliance with FCC limits) is described at:

http://www.kn4s.com/rf.html
RF Safety

(about halfway through the document)

My question is this:

Looking only at the two plates separated
by 10 cm, what is the impedance the
plates would present to a measuring
device in the hf spectrum? Is there a
simple way to calculate (estimate) the
impedance? Is the charging circuit time
constant a simple function of the
resistivity of air?

Ordinarily, a 10 megohm instrument would
load such a probe excessively because
the probe's impedance would be much
higher than 10 megohms.

Many thanks.

Chuck

Source record: 56714

On 40M SWR looks OK, but on 20M and Up I have a high SWR problem,

for example if I set 14.100 on the controller and TRCVR is on the same freq. SWR will be more then 2.5:1 , to get a better swr on 14.100, I have to go UP to 14.350 on the controller.

I can go to setup mode and change the driver lengths for the better SWR , but not sure if this is a right way to correct this problem ...

73,
Serge

Hi Chuck,

From their own page:
"the capacitance of its plates (1.8 pF)"

There are enough dimensional clues to compute this yourself, however.

>Is there a
>simple way to calculate (estimate) the
>impedance?

Xc = 1/(2 ï¿½ pi ï¿½ f ï¿½ C)

>Is the charging circuit time

No.

>Ordinarily, a 10 megohm instrument would
>load such a probe excessively because
>the probe's impedance would be much
>higher than 10 megohms.

The probe's resistance is what that is important, not its impedance
(which is to say the reactance is immaterial except as a scaling
factor as described). In that regard, the resistance is nearly
infinite for all practical purposes. A 10 Meg Ohm meter would take 10
ms to discharge in comparison to 0.1 ï¿½s to recharge. The circuit is a
clamping circuit (or peak detector) that automatically disconnects any
load from the probe. The actual load is the sag in the charge to the
capacitor. The ratio of charge/discharge insures that the volt meter
is quite transparent to the probe - unless you are after an accuracy
that borders on delusion.

This was rather a hip-shot guesstimate where I put the cap on the
wrong side of the isolation line's resistance. Anyway, there's still
a significant charge/discharge ratio that isolates the meter.

On the other hand, having called it a clamping circuit was a stretch
too. It is in fact a rather sloppy design in that regard (it is self
discharging) but this is not to say it lacks its intended utility.

Thanks for the info, Richard.

What I was looking for was information
on the charging part of the circuit. It
is not clear to me how or why the 1.8 pF
should recharge from the E-field in 0.1 uS.

The 0.1 uS time constant suggests a 5.6
megohm resistance in the charging
circuit. From where does that resistance
arise?

Put differently, what limits the rate at
which energy can be extracted from an
E-field through a capacitance of 1.8 pF?

Thanks.

Chuck

> --
> 73, Cecil
==========

The voltage between the relay contacts, when open, can be considerably less that the voltage at the end of the live wire relative to ground.

The capacitance between the open-circuit contacts of a reed relay is very small. And there is a larger capacitance between the two antenna wires on either side of the relay contacts. There is also capacitance between each of the two wires and ground.

If the input impedance of the wire on the remote side of the relay is not low then we have a voltage divider.

So the voltage which appears across the relay contacts can be considerably less than the volts between the live wire and ground.

If I remember correctly, the relay was located more than 1/4-wavelength along an end-fed wire on the 160m band. There was a random but not very long length of wire on the far side of the relay. The antenna was only about 20 feet above ground, ie., quite lossy. The details of what experiments took place I can't remember. Perhaps something to do with input impedance measurements and treating antenna wires as transmission lines.

If the open-circuit relay contacts did not arc over with 100 watts then it was more by design than good luck. ;o)

I've just had a search round my junk boxes to see if I stll have the reed relay. It was built into a small plastic box with a few decoupling capacitors and 3 binding posts. But, unhappily, no signs of it.

And my suggestion to operate a relay in an antenna wire via Radio Shack speaker wire stll holds good.

Regards, Reg, G4FGQ.

Lowest SWR doesn't usually occur at maximum gain or
lowest F/B ratio. Have you contacted the manufacturer
to see if it's really a problem?

You know just enough about RF to be DANGEROUS... Best leave the RF
Engineering to someone who knows what they are doing.....
By using any type of InBand Repeater, even if you did get enough signal
in each direction, Your system REQUIRES that your Antenna Aiming be
within about 500 ArcSeconds. How are you going to ensure that with
some kind of thing in between. Best you put the dish out where you can
see the appropriate location in the sky, the modem on the back of the
dish, and then bring the baseband, or data, to the connected systems
after that.

Thanks Reg, that makes sense now. That's quite different
from breaking a 1/2WL loop in the middle using a relay.
The voltages at each end of 1/2WL are 180 degrees out of
phase so the relay has to handle double the voltage existing
at the ends of the wires. A quick estimate of the voltages
at the ends of a 1/2WL dipole being driven by 100 watts is
1000 volts RMS. The relay would have to stand off almost
3kV PTP.

Hi Chuck,

As I said, an error with shooting from the hip. Besides, it is not the plates of the probe that are charging when compared to the 0.01ï¿½F cap, lead resistors, and meter. Rather, that probe capacitance (according to the author) is part of the reactance that is in series with the reactance of the diode. I'm not entirely convinced of the text's accuracy, but I'm not motivated to read it deeply either. The diode capacitance is a moving target and even its average is unsuitable for the analysis presented by the author.

The 0.1 uS number was drawn from a hat for an average over the HF region when the series resistance is low - guaranteed for at least half a cycle when there is no stored charge. This returns us to the interpretation of the clamping circuit, but this interpretation remains tenuous.

>Put differently, what limits the rate at
>which energy can be extracted from an
>E-field through a capacitance of 1.8 pF?

The source resistance, which in this case is the field. To describe further embarks us upon the nature of extracting the signal's strength from the field, and then on to matters of matching load to the source. Beyond that, it becomes an issue of efficiency.

However, with respect to the proposed probe, matching and efficiency are not a concern. The point of the 0.01 capacitor (not the plate structure of the probe) is to store sufficient charge (undrained by the meter load) so as to effectively become an open circuit to power demand - for half a cycle at least in the design offered. The point of a probe is to not disturb the field (not take power, and to return as much energy as was extracted).

186. Confidence limits for noise measurement

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-08 22:08:20 UTC
From: Owen Duffy <owen@no.where>
Message-ID: <bb90b2huubaqatep95s0082kkb4ru2e354@4ax.com>
Source record: 56723

I am trying to estimate the confidence limits for measurement of white noise passed through a limited band filter.

In the first instance, can we consider the filter to be an ideal low pass filter.

The noise voltage can be though of as a stream of instantaneous values with Gaussian distribution, mean of zero, and standard deviation equal to the RMS voltage.

If I take samples of this waveform, I should be able to calculate the noise power (given the resistance). The noise power is proportional to the variance of these samples, and the constant of proportionality is 1/R.

Shannon's Information Theory says to me that I need to sample the waveform at least at double the highest frequency of any component (the break point of the low pass filter).

It seems to me that what I am doing in statistical terms is taking a limited set of samples and using it to estimate the population variance (and hence the noise power in a resistor).

So, I can never be absolutely certain that my set of samples will give the same variance as the population that I sampled.

I should expect that on repeated measurement of the same source, that there will be variation, and that a component of that variation is the chance selection of set of samples on which the estimate was based.

It seems reasonable to assume that taking more samples should give me higher confidence that my estimate is closer to the real phenomena, the population variance.

So, I am looking for a predictor of the relationship between sample variance (the "measured" power) and population variance (the "actual" power), number of samples, and confidence level.

The statistic Chi^2=(N-1)*S^2/sigma^2 (where S^2 is the sample variance and sigma^2 is the population variance) seems a possible solution. The distribution of Chi^2 is well known.

So I have plotted values for the confidence limits indicated by that approach, the plot is at http://www.vk1od.net/fsm/RmsConfidenceLimit01.gif . The x axis value of number of samples relates to the minimum number of samples to capture the information in the filtered output (in the sense of Shannon), ie bandwidth*2.

It seems to me that this should also apply to a noise source that has been passed through a bandpass filter (with a lower break point >0), so long as the sampling rate is sufficient for the highest frequency, but that the number of samples used for the graph lookup is bandwidth*2.

I understand that there are other sources of error, this note is focused on choice of appropriate number of samples (or integration time) to manage the variation in the sampling process due to chance.

Am I on the right track?

Comments appreciated.

Owen

PS: This is not entirely off topic, I am measuring ambient noise from a receiving system, and antenna performance assessment is the purpose.

Hi Owen,

This will possibly be your greatest source of error, the clipping of
the spectrum. In Fourier Analysis, the operation is called
"windowing" and there are a world of window shapes that offer either
excellent frequency resolution at the cost of amplitude accuracy, or
the t'other way 'round. Insofar as the window shape, this deviates
from an "ideal" filter response, but then an "ideal" filter response
(infinite skirt) does not guarantee accuracy.

Blackman and Tukey in their seminal work, "The Measurement of Power
Spectra" (1958) assert that
"a realistic white noise spectrum must be effectively
band-limited by an asymptotic falloff at least as fast as 1/fï¿½."

Consider the discussion at:
http://www.lds-group.com/docs/site_documents/AN014%20Understanding%20FFT%20Windows.pdf

>Shannon's Information Theory says to me that I need to sample the
>waveform at least at double the highest frequency of any component
>(the break point of the low pass filter).

That's Nyquist sampling rate at slightly more than double than Fmax.
Shannon predicts the bit error rate for a signal to noise ratio.

>It seems to me that what I am doing in statistical terms is taking a
>limited set of samples and using it to estimate the population
>variance (and hence the noise power in a resistor).

Seeing that the RMS voltage is applied fully to the resistance,
shouldn't that be signal + noise power in a resistor? The noise in
this sense only describes the deviation from the distributions' shape.

>So I have plotted values for the confidence limits indicated by that

When I've done brute force noise reduction through ever increasing samples, it always appeared to follow a square law relationship.

>Am I on the right track?

What are you using as a source of noise?

In this case, the KTB noise due to the loads own resistance is so
small as to be insignificant and not require a correct to be applied.

I expected that, and the radioastronomy folk seem to work on that
basis from Dicke's work, if I understand it correctly.

>
>>Am I on the right track?
>
>What are you using as a source of noise?

Noise from the real world which I understand is not exactly white, but
I figure that if I understand the behavior from a white noise point of
view, the answer will be very close for noise that resembles white
noise.

The noise is audio output from an SSB receiver (operating below AGC
gain compression threshold) that, if you like, is acting as a linear
downconverter with a narrow pass band filter. Typically, the passband
is 300-2400Hz. The sampling is done in a PC sound card at a rate of
11kHz. The application here is using these samples to synthesise a
"true RMS voltmeter".

The question is how many samples, or how long an integration time at a
given bandwidth, is required to reduce the likely contribution of
chance to the sampling process below, say 0.1dB, at a confidence level
of, say 90% (in a two tailed test).

Thanks for your response Richard.

Owen

Hi Owen,

I was not thinking of thermal noise (actually, I've been quite deeply involved in studying phonon interaction, but not to this purpose). Rather, I was offering that if you integrate under the curve of the gaussian distribution, and compare to the computed/measured noise power, then and only then through that difference would you resolve error. Of course, this may be a description of what you have already offered in previous discussion.

>>What are you using as a source of noise?
>
>Noise from the real world which I understand is not exactly white, but
>I figure that if I understand the behavior from a white noise point of
>view, the answer will be very close for noise that resembles white
>noise.
>
>The noise is audio output from an SSB receiver (operating below AGC
>gain compression threshold) that, if you like, is acting as a linear
>downconverter with a narrow pass band filter. Typically, the passband
>is 300-2400Hz. The sampling is done in a PC sound card at a rate of
>11kHz. The application here is using these samples to synthesise a
>"true RMS voltmeter".

I've used both biased Zeners and weakly illuminated Photomultiplier Tubes. The PMT doesn't offer much power, but it is flat out to the 100s of MHz. Another precision method is to load each output of a ring counter (as big a ring as possible) with a random selection of resistor values and feed them into a summing junction. This is especially useful in the AF region.

Owen, I can't understand your problem. Could you condense it? I would just take every measurement to be correct at the time it was made and stop worrying about it.

Have some faith in your measuring instruments. Variation in the presense of noise can be expected. If you want to be more accurate, sit and watch the meter for 30 seconds and make a mental average. If the noise statistics are stable then you will obtain the same answer five minutes later. This will give you confidence in the measurements. Which is what you are looking for.

"Statistics" is amongst the most useful of the many branches of mathematics. But it comes to an end when trying to estimate the confidence to be placed in setting confidence limits. If you have a few months to spare, refer to the works of Sir Ronald Arthur Fisher, the greatest of all Statisticians. He was involved with genetics, medicine, agriculture, weather, engineering, etc.

(You remind me of Gossett and the "t" distribution. Early in the 20th century Gossett was a chemist/mathematician working in the quality control department of the famous Guinness brewery in Dublin. In his work he derived the distribution of "t" which allowed confidence limits to be set up for the normal distribution based on the measurements on small samples themselves. He realised he had invented and mathematically proved a long-wanted, important, practical procedure. But his powerful employer could not allow chemistry and mathematics to be associated with yeast, hops and all the other natural flavoured ingredients in their beer so they barred him from publishing a learned paper on the subject under his own name. So he used the nom-de-plume "Student". Ever since then the name of his statistical distribution amongst scientists, engineers and everyone involved with statistics has been known as "Student's t".

Guinness, untainted by Gossett, is still a popular drink in English and Irish pubs.)

Student's "t" will very likely appear in the solution to your problem, whatever it is.

Reg.

I am designing the instrument. I am exploring the number of samples
required to reduce the effect of chance on the measurement result (in
respect of the sampling issue) to an acceptable figure.

Well, despite my name and Irish father, there is not a skerrick of
Irish in me, or Guiness for that matter.

>
>Student's "t" will very likely appear in the solution to your problem,
>whatever it is.

Student's t distribution is a probability distribution of the mean of
a sample of normally distributed random numbers.

The mean of noise is 0 (unless it contains DC, which is not noise).

The Chi-square distribution (which I proposed in the original post) is
the probability distribution of the variance of a sample of normally
distributed random numbers.

The variance of noise voltage is the RMS^2, or proportional to power,
and so is of interest.

hi

So if i buy some coax and want to do a 'sweep test to see if the connectors and cable is 'ok'

i figured i'd buy a mfj or palastar etc seems most only do hf and mfj while up to 440 kinda ends there

so i'd like to test up to at least 1.2g

anyone know of any units like the above that are less then the megabucks pro gear?

thanks

193. EZNEC Question

Is there an upper frequency limit that EZNEC can calculate with? If so,
how high can one go? Will it do reasonably well up to say 902 MHz?

No, there's no upper or lower frequency limit.

However, EZNEC results are only as good as the model. As frequency increases it's increasingly difficult to make a model which adequately imitates the real antenna.

Just for interest did you try my last suggestion with measuring power at source end load ends?

The problem with cheap gear is of course accuracy. What kind of results are you looking for? You should be able to measure maybe 0.5dB problems using power measuring as previously mentioned.

FWIW, my Dodge van's installed radio antenna went bad (open shield, way out of reach), so I put a Moto-to-BNC adapter on the back of the radio and dropped a pigtail of RG-58 down by the heater outlet. I connected my MFJ 2m/440 magmount to the radio via the pigtail. Works quite well. If I want to use it for ham radio, a couple of quick connector twists is all it takes.

Added bonus: When driving out of town, away from strong signals and low overheads, I unscrew the stock MFJ whip, exchange it for a straight whip several feet long and get outstanding broadcast reception, both AM & FM.

There's an example of a 4ele 2m J-fed yagi in the MMANA files. It has a
gain of 7dBd. Free space pattern is skewed up by 1 degree, but a real
ground will do that anyway.

I don't know of any commercial versions.

Roy,

I just wanted to butt in to say that your EZNEC is a fine program. Just started playing with it (ARRL version). Very user friendly...and your "test drive" is phenomenal.

I must say, since I left ham radio back in the late 70's, I am very surprised that antenna modeling is within the reach of someone of limited technical background like me.

Great job!
You've done a lot for my "new" favorite hobby.

Thanks!

John
AB8WH

PS, I will be purchasing the full program.

Source record: 56646

Well.....this isn't my usual 2m set-up,BUT it is an extra set-up
for the commute. I use the
home/base set up in my living room at times for convience. I have been
using a 2m hustler 5/8 wave,mag mount on my radiator cover with five
watts to reach a local repeater. I can reach
this repeater with my handie-talkie. For some UNKNOWN reason this
mobile radio set up
has been having a "squeal" on TRANSMIT. I can't figure out WHAT is
causing this noise!
It's starting to drive me crazy. Handie-talkie......no problems. My 2m
shack radio...with an outdoor antenna,no problem. The SWR 's are fine.
I've tried turning off and on the computor or the cable TV to see if
those were the sources....no luck. I've moved the antenna around to
different places on the rad. cover...?? Tried ferrite on the power
leads.....used a battery,it
dimished a little bit with the battery,but it is STILL THERE!!!!!!
Am I doomed to either the Handie-talkie OR go uyp stairs to the
shack to use the 2m's??? Sometimes I find a "signal"?,on the recieve
meter,a small one,
that CAN'T be squalched out either! darn crazy V-8000 I'm
picking up something somewhere.

It's ONLY on transmit. damn....I have to find out "WHY" maybe my
radio needs a ground?.....antenna AND RADIO. I feel lost with
this one.

------------ REPLY SEPARATOR ------------

There are several possibilities on this kind of problem.

Some things to try:

1. Put one or more snap-on ferrites on the coax. You may have an "RF in the shack" problem which is feeding back into the mike circuit. If this fixes it, you have an antenna problem, most likely a poor, i.e. non-resonant ground.

2. Add some more coax and get the TX farther away from the antenna.

3. Try it on a dummy load. Is the squeal still there? If so, a possible power supply problem.

Good luck.

I build one for 2 meters some years ago. The element was 1/4 copper tubing with an air spaced variable at the end, and fed with a modified gamma match. The antenna was about 3 inches tall, and it fit on top of my van without hitting the garage on the way in.

I did one set of rough comparisons between it and a 1/4 wave mag mount vertical. (A buddy gave readings from his S-meter) The vertical was better, but by less than 3 dB. This was not really a good test, but probably provided a valid assesment of which was better. However, the DDRR provided quite acceptable service into the local repeater, and I used the antenna until I sold the van.

215. Quarterwave vertical with radials

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-09 19:57:18 UTC
From: David <nospam@nospam>
Message-ID: <UNOdnZVbXoTO_CzZRVnyvg@bt.com>
Source record: 56652

Can someone provide a full description of how a quarterwave vertical antenna with radials works? Length of radials is also a quarterwave.

I find that many books give a good description of antennas like the Yagi, and then suddenly become very vague when describing the quarterwave vertical. Books
refer to image theory where an image of the radiating element is produced by the radials, and show a spear shape going into the ground. Some say the radials are the other half of a dipole.

What difference does it make if the radials are in free space or in the ground? Some articles claim that the radials tend not radiate because they cancel out, while other other articles claim that the radials simulate a ground plane and reflect the radio wave. Can you explain this contradiction?

The vertical element is usually called the radiating element. How well do the radials radiate? The same magnitude of current flows into the vertical element as the radials, although the current into the radials is split.

A normal ground plane is a large sheet of metal that reflects the radio wave emitted by the radiating element. If there are four radials, each a quarterwave long, do the radials form a ground plane? Or is there too much of a gap for them to form a ground plane?

If the radials are disconnected and taken away, with the vertical quarterwave element still connected to centre conductor, do I still have a radiating element? What happens to the SWR?

Yup, points to Cecil for realizing this.

Based on similar turns of phrase in a private E-mail message sent to me recently (of the usual, unhinged, "I didn't ask to be welcomed to this newsgroup!" variety), I can say with great likelihood that the perpetrator of this forgery is the individual who posts on rec.radio.amateur.policy with the E-mail address "wussyroger@yahoo.com." I sent a complaint to alt.net and altopia.com in case they caught the poster in their logs.

It seems that we've really, really hit a raw nerve here among the unbalanced trolls who populate rec.radio.amateur.policy. They very much seem to fear the prospect that a new, moderated discussion newsgroup for amateur radio stands a good chance of getting created, one that will leave them behind.

I suspect that there will continue to be a storm of retaliatory forgeries for some time to come, at least through the fall. As I said previously, check the headers. If something appears to be from me, and is not from Novia/Newscene, then it's a forgery. Check also for misspellings, poor grammar, and obscene language.

==========
The first thing to do is calibrate the instrument against a standard noise source. Immediately, the uncertainty in the standard is transferred to the instrument - plus some more uncertainty due to the manner in which the standard and instrument are associated.

Does the instrument read in watts, decibels, or what?

The second thing to do is to be verbally and numerically more precise about "to reduce the effect of chance on the measurement result to an acceptable figure."

At the outset you should define the acceptable figure. What effects? In what units is the acceptable figure?

It is then not a difficult matter to decide the number of measurements, by taking samples, to give a predetermined level of confidence in the average or mean. But I have the feeling you are over-flogging the issue. You don't really have a problem.

Picture a half wave dipole, with a balanced feed. Two elements
perform the radiation and there is zero voltage swing at the exact
center of the dipole (though there is peak resonant current passing
through the center).

Now, cut that dipole exactly in half, and place a mirror at the half
way point. Half of the balanced feed line can be replaced by an
unbalanced (coaxial) feed line of half the impedance, since two of
those, with their shields connected and the center conductors out of
phase, would make a balanced feed line.

The radiation from the quarter wave half of the dipole is reflected by
the mirror to produce an an image of the missing half of the dipole.
The radials at the end of the quarter wave dipole act as the mirror.
This effect is pretty efficient as long as the radials are at least
1/4 wavelength long.

Hi David,

Someone can, and someone already has, but that hasn't helped you has
it? The following statements suggest so:

>I find that many books give a good description of antennas like the Yagi,
>and then suddenly become very vague when describing the quarterwave
>vertical.

It isn't vague, unless you've been saddled with poor references. On
the other hand there is not much to say when you are working with
elementary monopoles and dipoles. Yagis, in this sense, have much to
be discussed.

>Books
>refer to image theory where an image of the radiating element is produced by
>the radials, and show a spear shape going into the ground. Some say the
>radials are the other half of a dipole.

Radials being the "other half" simply reveals that the monopole
(especially when elevated) is a vertical dipole.

>
>What difference does it make if the radials are in free space or in the
>ground?

About 3dB.

>Some articles claim that the radials tend not radiate because they
>cancel out,

All parts of an antenna radiates, the radials' contributions cancel -
at a distance.

>while other other articles claim that the radials simulate a
>ground plane and reflect the radio wave. Can you explain this contradiction?

Poor references. The radials simply serve for drivepoint Z
consideration (we already agree that their contribution to radiation
cancel). For all practical purposes, the "ground plane" would have to
extend out 5 to more wavelengths to affect the lobe characteristics of
radiation.

>The vertical element is usually called the radiating element. How well do
>the radials radiate?

Perfectly, or as well as the "radiator" presuming they all exhibit
similar construction.

>The same magnitude of current flows into the vertical
>element as the radials, although the current into the radials is split.
>
>A normal ground plane is a large sheet of metal that reflects the radio wave
>emitted by the radiating element. If there are four radials, each a
>quarterwave long, do the radials form a ground plane? Or is there too much
>of a gap for them to form a ground plane?

They are simply not long enough, and certainly don't exhibit near the
coverage (the gap you describe) as does a plane of metal (or
seawater).

>If the radials are disconnected and taken away, with the vertical
>quarterwave element still connected to centre conductor, do I still have a
>radiating element?

A poor one, but given the wheel of fortune, the feedline could make up
the difference.

>What happens to the SWR?

It usually goes ballistic, but again, with ground nearby, you could be
heating worms and find the SWR at a comfortable value.

Try the ARRL Antenna Book. In general, symetrical elevated
radials don't radiate. In general, ground mounted radials
are lossy.

Yes, absolutely. You should get several square feet of conductive surface
for a counterpoise -- sort of like the car roof the magmount is expecting.
(I had good luck with a metal TV-tray.)

I haven't used a Smith Chart in over 30 years, and to say the least, I'm a bit rusty. I'm thinking there must be computer programs that can do the calculations with values you just plugs in. Any recommendations? I'm specifically interested in finding the impedances of antenna whips much shorter than 1/4 wave.

Oh, it's a forgery alright, unless he doesn't know how to spell his own name. He spelled it correctly once, mispelled it twice, and none of the domains resolve. And the sender was not using his ISP, which is easy to find.

A little attention to details, checking of headers, plus google goes a long way folks.

My experience with Navy UHF (225 - 400 MHz) antennas bears this out. There are two vertically polarized omni antennas that appear in great numbers: AT-150, which is a true dipole, fed with coax through an internal balun, and the AS-390, which is a quarter-wave whip with eight "spider-leg" radials. It is fed directly. They perform equally well and the system designer's choice is generally based on mounting considerations.

There are over a dozen UHF antennas, some in stacked combinations called "stovepipes", but of the single-unit antennas, the AT-150 and the AS-390 are among the most common.

230. Re: Quarterwave vertical with radials

Image theory is for a perfect groundplane e.g. large area metal sheet. The wave emitted by the vertical radiating element is reflected by the ground plane.

Image theory as I see it follows. Wave emitted by vertical element is the incident wave that hits ground plane, inducing currents in the ground plane. Currents flowing in skin depth of ground plane emit a wave of opposite polarity to cancel out the wave at the boundary of the ground plane, thus making the electric field in the ground plane zero. The wave of opposite polarity is the reflected wave. The reflected wave appears to be coming from an image antenna. Image theory is a mathematical model for solving antenna simulations where there is a monopole over a ground plane.

How do the radials reflect the wave? If they are not a good enough ground plane because of the gap, how do they reflect? I cannot see the transition from ground plane to radials, when looking at image theory.

David wrote:
> Can someone provide a full description of how a quarterwave vertical antenna
> with radials works? Length of radials is also a quarterwave.

When you connect a source or feedline to this antenna, the same amount of current which flows into the vertical flows into the radials. First consider one which is well above the ground. The current in each pair of radials flows in physically opposite directions. So the radiation from the radials cancels completely at right angles to the radials, and nearly completely in other directions. The vertical acts like a dipole except with half the length and twice the current, resulting in the same pattern and field strength as a dipole.

If the radials are buried, the current into the radials spreads into the ground. Current through the ground results in loss due to the ground's resistance. Therefore many radials are required to force the majority of current to flow in the wires rather than the ground. This is particularly important close to the vertical where the current density is high.

> I find that many books give a good description of antennas like the Yagi,
> and then suddenly become very vague when describing the quarterwave
> vertical. Books
> refer to image theory where an image of the radiating element is produced by
> the radials, and show a spear shape going into the ground. Some say the
> radials are the other half of a dipole.

That's probably because the authors don't understand some fundamental principles, or else they oversimplify to the point where the explanation isn't correct. Radials are nothing more nor less than conductors carrying current, and radiate accordingly. But they're placed and fed so the radiation nearly cancels.

> What difference does it make if the radials are in free space or in the
> ground? Some articles claim that the radials tend not radiate because they
> cancel out, while other other articles claim that the radials simulate a
> ground plane and reflect the radio wave. Can you explain this contradiction?

It's a lousy explanation of what's going on, written by someone who doesn't really understand. When the radiation from the vertical strikes the ground, it's reflected. If the ground were perfectly conductive, flat, and infinite in extent, it would be like a mirror. But real ground isn't any of these things, so a mirror is a very poor representation. The reflection from the ground causes the formation of a vertical radiation pattern which looks very different from what you'd get from a perfect, mirror-like ground, with the exception that salt water does

approximate a mirror reasonably well. Except at high radiation angles,
this reflection takes place well beyond any radials, so the radials
don't contribute at all except at high angles.

> The vertical element is usually called the radiating element. How well do
> the radials radiate? The same magnitude of current flows into the vertical
> element as the radials, although the current into the radials is split.

Correct. See above.

> A normal ground plane is a large sheet of metal that reflects the radio wave
> emitted by the radiating element.

"Normal"? Where have you seen an antenna mounted over a metal ground
plane many wavelengths in diameter? Perhaps a UHF antenna in the middle
of the top of a car, but that's about it.

> If there are four radials, each a
> quarterwave long, do the radials form a ground plane?

Radials do not form a flat metal conductor many wavelengths in diameter,
if that's what you're asking. And they don't reflect the radiation from
the vertical, either.

> Or is there too much
> of a gap for them to form a ground plane?

They're much too short to reflect the radiation. Or are there other
properties you require for something to qualify as a "ground plane"?

> If the radials are disconnected and taken away, with the vertical
> quarterwave element still connected to centre conductor, do I still have a
> radiating element?

Yes. Whatever current you put into the element, an equal current flows
elsewhere. If the element is connected to a coax transmission line, it
flows down the outside of the coax, so the coax radiates just like the
element. If you just plug it into a coax connector on a transmitter, the
current flows out of the connector onto the outside of the transmitter,
so it and the path to the Earth radiate just like the element. Current
on a conductor creates radiation. It doesn't matter one bit whether you
declare the conductor to be "ground", a "ground plane", or a "transmitter".

What happens to the SWR?

You now have an asymmetrical antenna. One "half" is the vertical and the
other is whatever conductor the return current flows on. The SWR will
almost certainly be different than it was for a typical ground plane
antenna.

Actually, it's not the same source, but it's fun to mess with morons.

So I'll have 2 separate people to call about tomorrow.

Note that I said call. If you really want to get action from an ISP, email everything you can dig up to abuse@whatever_isp.com. Be sure to include full headers from the incident; if you don't, they will have nothing to work from.

Then give a call to tech support and tell them what's going on, and where you sent the information. If they don't give you satisfaction, ask to speak to a manager or to engineering support. They will usually get you the person you need to resolve the problem. It's also a good idea to call during regular business hours for the time zone they are located in.

The contradiction over antenna radials continues. One posting says that the radials acts as a mirror and reflect the wave, another post says the radials do not reflect - that the radials are simply positioned so that the radiation from them cancels out.

Reg, I think you have missed my point. Because of the random nature of white noise, an attempt to measure the noise source by sampling the noise for a short period introduces an error due to the sampling process. That sampling error is related to the quantity of "information" gathered by the sampling process, ie the length of "integration" or number of samples.

The issue is not about absolute calibration, it is about one source of error in measuring a white noise source, and quantification of bounds on that error to a level of confidence.

>
>Does the instrument read in watts, decibels, or what?
>
>The second thing to do is to be verbally and numerically more precise
>about "to reduce the effect of chance on the measurement result to an
>acceptable figure."

I am sorry if that is wordy, but I think it is precise in expressing the problem.

To give a specific application, suppose that I want to do an receiver system performance test by comparing noise from one cosmic noise source with quiet sky, and I expect the variation with my G/T to be 0.5dB.

>
>At the outset you should define the acceptable figure. What effects?
>In what units is the acceptable figure?

The acceptable figure will depend on the application, I am trying to understand the principle.

>It is then not a difficult matter to decide the number of
>measurements, by taking samples, to give a predetermined level of
>confidence in the average or mean. But I have the feeling you are
>over-flogging the issue. You don't really have a problem.

So, coming back to the application above, I note that successive measurements of the same white noise source passed through a limited bandwidth filter have variation from measurement to measurement, and that variation is related to the length of time that length of "integration" time or number of samples used for each measurement.

In trying to understand this relationship, I explored the use of the Chi-square distribution as discussed in my initial posting.

In looking for more information on that relationship, I found Dicke being quoted with an estimate of the sensitivity of a radiometer as the minimum detectable signal being the one in which the mean deflection of the output indicator is equal to the standard deviation of the fluctuations about the mean deflection of the indicator. He is quoted as saying:

mean(delta-T)= (Beta * Tn) /(delta-v * t)^0.5

where delta-T is the minimum detectable signal; Beta is a constant of proportionality that depends on the receiver and is usually in the range 1 to 2; Tn is the receiving system noise temperature; delta-v is the pre-detection receiver bandwidth; and t is the post detection integration time constant.

(I do not have a derivation of Dicke's formula.)

This suggests that an estimate of the error (in dB) due to the sampling process is 10*log(1+Beta /(delta-v * t)^0.5).

I have plotted the above expression at Beta=2 over the plots that I did based on the Chi-square distribution, they are at http://www.vk1od.net/fsm/RmsConfidenceLimit03.gif . You will see that the Dicke (Beta=2) line follows (ie it pretty much obscures by overwriting) my Chi-square based 95% confidence line. It appears that the two methods arrive at similar answers.

Dicke's Beta seems to be determined empiracally. Varying Beta has the same effect as changing the confidence level in my Chi-square based estimator.

Owen

PS: Still remains relevant to antennas, I am measuring the performance of a receiver system, which includes the antenna and alll noise sources.

Thanks for the additional comments,
Richard. The probe seems remarkable in
being able to utilize a 10 megohm DMM to
measure an RF field given that a DMM
would not work at all to measure a
static electric field.

Static field measurements are almost
always done with extremely high input
resistance electrometers, fieldmeters,
and field mills. All of these usually
incorporate voltage follower op amps or
something similar to keep the input
resistance above 10 exp(13) ohms.
Hooking up a DMM would quickly discharge
any electrodes in the field.

Thanks again.

Chuck

I should have mentioned that I don't understand why the Beta factor
would vary from receiver to receiver. It seems that it was determined
empirically. If the indicating instrument was a meter pointer observed
by a person, perhaps Beta might have captured the observer effects
more than the equipment.

Hi David,

Well, this is not an opinion based outcome, and interpretation is even
less forgiving.

Radials that "act as a mirror" are fantasy for radial lengths less
than 5 wavelengths at less than several hundred in count. Simple
geometry and trig are suitable to observe this.

Radials that "are simply positioned" certainly outnumber those that
are not. A vertical with two radials is sufficient to do the job, and
simply positioning them at 180ï¿½ to one another is enough to insure
their radiation from canceling at a distance.

Now, when we regard the first claim in light of the second, it is
amazing how much mirror-like quality those two radials have (which
sort of puts the bronx cheer to the mirror claim).

Hi David,

Well, given your repetition of "ground plane," be cautioned that is
not one-and-the-same meaning for radials (even if they are called part
of a ground plane antenna).

Hi to all,

>From the help file of EZNEC, I copy this sentence:

''The ground reflections which cause the low-angle pattern reflections
take place farther from the antenna than most common radial ground
systems extend, so ground radial systems have little or no effect on
the ground reflection phenomenon.''

My question: Is this phenomenon dependent of the frequency? In other
words, will the first reflexion point be farther away with lowering of
the frequency or about at the same distance, independently of the
wavelength**?

**In that case, the ''long'' radials of AM broadcasting verticals 'may'
also become reflectors...

I put up a shielded link loop several years ago laying on the roof near the gutters with part goint to close trees in the front yard as a receiving antenna several years ago. It was something on the order of 180 feet long as written up by AB0X in a 1989 CQ. I had just gotten my Amp Supply LK 500NTC and was listening to a CX on 75. I thought I set it to RX on the antenna and transmit on my half square but I worked him on the shielded loop. He was only a few DB stronger on the half square.

Did'nt burn the roof off but made sure I did not do that again HI.

Effectively, yes.

A metallic surface (your "sheet of metal") can be replaced by a partially metallic surface -- within limits. If you keep the size of any gap under 1/10 wavelength, the surface will appear solid. This I know from satellite reflector work.

The use of four radials appears to be a compromise for using a solid surface, but it obviously works. The RF sees these radial wires and behaves like we want. I think adding more radials will always make a better counterpoise, but I also think you reach the point of diminishing returns pretty quickly. (We aren't the first ones to speculate about this, after all :-)

For a given antenna height and elevation angle, it's the same distance from the antenna.

Imagine yourself at some point on the antenna, say at the middle of a vertical antenna. Direct your gaze at an angle of 10 degrees below horizontal. Radiation traveling from the antenna at that angle will strike the ground at the point where your gaze does, and after reflection it will be going upward at an angle of 10 degrees above horizontal. The overall elevation pattern at 10 degrees elevation angle is formed by the sum of a direct ray going upward at 10 degrees and one going downward 10 degrees below horizontal, reflecting off the ground, and adding to it at a distant point. The lower the angle or the higher on the antenna you are, the farther the reflection point. Antenna programs repeat this process for every "segment", that is, points all along the antenna, to get the total field.

So where does that reflection take place? Let's use your example of an AM broadcast antenna. Some broadcasters, I believe, use verticals which are around a half wavelength high. Suppose the frequency is 1 MHz, so the wavelength is 300 meters, and a half wave antenna would be about 150 meters high. Broadcast radials are, I think, around a half wavelength long. So the field from half way up the antenna would just strike the end of the radial field, using this simplified model, at a downward angle of arctan(75/150) ~ 26 degrees. Any radiation from the center of the vertical at an angle below 26 degrees would reflect beyond the radial field, so the elevation pattern for all angles below 26 degrees

would be independent of the radial field. Likewise, radiation at 26 degrees from any portion of the antenna above half way up would strike the ground even farther away. Ironically, vertically polarized reflection at angles above this aren't too bad off plain dirt, so the radials don't help as much as you might think even at high angles. It's low angle reflections that really suffer when polarization is vertical, and those are the ones missing the radial field.

This model is oversimplified, not taking into account the fact that the wavelength is large relative to some of the dimensions being considered or the considerable skin depth of the ground. The "NEC radial" option of NEC and EZNEC uses just this kind of analysis with the ground in the region of the radial field being assumed uniformly conductive, and I discourage its use. It's more accurate to model very slightly elevated radial wires where the fields from the wire currents make their true contribution. But when you do, you'll find that the radials still don't have much impact on the lower angle portion of the pattern.

In daylight, with vertical LF and MF antennas, all radiation at an
angle above 0 dgrees and that reflected from the ground, whuch is most
of it, is wasted and generally unwanted.

Only the groundwave is useful.

At night a virtue is sometimes made out of a vice.

==========

What everybody forgets about is that the velocity factor along
ground-mounted radial wires is about half of the free-space value.

Consequently, the 1/4-wave resonant length is crudely only half of the
elevated value.

On the other hand, the resonant length is very non-critical because Q
is very small - Q is only 2 or 3 and is even smaller at the high end
of the HF band.

Actually, at HF and average ground, the velocity factor below the ground is about 1/4 to 1/5 the free space value. And no resonance at all is usually apparent because of the high loss.

EZNEC isn't among the "everybody" who's forgotten it. Choose any real ground, open the Utilities menu and click Ground Info, and you'll see the velocity factor along with other information. But it's seldom of any practical use.

Just last month, with four elevated 40 meter radials 6 feet high, the antenna was about 5 dB weaker than the very same antenna with 16 radials laid directly against soil.

This basic result repeated at three different soil locations on three different bands, 160, 80, and 40, so it is not a fluke.

In my last quick measurement on 7MHz:

16 long radials directly on the earth (no attempt to make resonant since they have very low Q) 0dB reference

8 long radials on the ground -1.3dB reference

4 long radials on the ground -3dB reference

4 resonant elevated radials at six feet -5.6dB reference

While the above is generally true for broadcasting...

I, like hundreds of others, can work 1000 miles or more during mid-day in winter on 160 meters. I, like many others, can work thousands of miles in mid morning or late afternoon. It isn't unusual to hear and work west coast stations that are 2000 miles away at 10 or 11 AM local time, and that sure isn't zero degree takeoff stuff.

By the way the vast majority of AM BC stations use tower somewhere around 1/4 wl tall. There is nothing to be gained by going taller compared to the extra installation and upkeep expenses. AM BC stations used to use 5/8th wave verticals in early years of broadcasting, but they quickly learned that was actually a disadvantage because the earth around the antenna wasn't good enough to allow the full gain. All the extra height did was increase fading at modest distances.

That makes sense.

For 80 meters we'd have an antenna 40 times taller and thicker, or a 10
inch diameter copper pipe element 10 feet above a metal plate a
wavelength in radius as a groundplane, and only be about 3dB down from
a 1/4 wl vertical.

I'll run right out and build one. :-)

Sometimes the more I learn the less I know.

I have dabbled a lot along these lines in the last few months. I have determined my methods are faulty.

When I compare two or more antennas for gain I have no means to measure the actual gain because I really don't know what the radiation pattern is in real life.

However, comparing measured gains with calculated gains has given me more confidence in the EZNEC calculations.

I have limited my test antenna to a 30 foot vertical with radials consisting of electrical extent ion cords connected in parallel stretched out on the ground. I seem to be manipulating the take off angle and the impedance of the feed by adding and subtracting these radials. The vertical seems to be more quiet (fewer signals) than a dipole but pretty much the same strength on those it hears. The reference dipole is the 40M section of my CushCraft A3S Beam at about 40 feet.

The only certain conclusions I have made are that getting high confidence numbers about radials is a lot of work and probably beyond my resources. The ARRL Antenna Handbook and EZNEC are usually right.

re: Usually right...
If you lie to EZNEC it will lie right back to you with an even bigger lie. Be very careful with assumptions!

The Antenna Handbook...
There is still the unresolved issue of conjugate matching. I noted last week or so that a copy of Walter Maxwell's book that retailed for $19.95 went for about $75 on EBAY.

Apples and oranges. The antennas to be compared should be identical
except for height. 0.04WL on 40m can hardly be considered to be
"elevated". To be considered to be truly elevated, the radials
should be at least 1/2WL in the air. Please compare a ground mounted
vertical with 4 radials to the same truly elevated-radial 40m vertical
whose 4 radials are 70 feet in the air.

Here's what EZNEC says about a 4 radial vertical on 40m.

Radials one foot above ground: max gain is -0.34 dBi

Radials 70 feet above ground: max gain is 2.51 dBi

Here's a question overflowing from eHam.net and it's
not a trick question.

Assume that the radiating portion of a 40m vertical
is made out of 33 feet of RG-213 and the braid is
the radiator. The center conductor of the coax is
left floating at both ends. How much RF voltage
and/or current will be induced in that center wire
when using the outside braid as the radiator for
100 watt operation? How much of an EM field can
exist inside the coax braid?

Picture a half wave disk of metal as the ground plane, producing the
inverted image of the vertical. Then imagine thin radial slots spread
around the vertical. Since these slots do not cross any current path
that is needed to produce the image, they have little effect on the
image. Widen those slots, and decrease the number of them, and
eventually you get to a ground radial system with only a few radials.
There has to be a transition point, where the radials are only a
poor approximation of the original disk. The question is, how well
must you approximate the disk to get a reasonable approximation of the
far field radiation pattern it would have helped produce?

Actually, on elevated antennas (as in the usual VHF setup), just two quarter-wave radials 180 degrees apart is almost indistinguishable from 4 or more radials. EZNEC shows very little change in terminal impedance and pattern by removing two radials from a 4 radial ground plane.

I once used copper tape on a window to make a ground plane vertical like that for 70cm. It worked very well.

Cheers,
John

Me,

First of all, thanks a lot for your reply. Secondly, Globalstar
constelation is NOT geostationary, thus the antenna is an
omnidirectional one. Also, I do have the means to point the reradiating
antenna and/or RF repeater towards the real omnidirectional one.

Regards,
Pablo

Tnx all who replied.
Kevin, have decided to try to stay away from "looping" the house since it's guttered and other electronics inside.
Now planning to try a triangular "loop" between 2 sides of house and a single support about 75' away - would make the total about 220' of wire, fed at one corner, about 30' AGL. (When it gets below 100 outside....)

Hi Pablo

I was going to comment on this but didnt get around to it.

I am surpised by your comment about the satellite system being LEO's rather than geostationary. Shows how much I have kept up with such systems! I see now it is the Globalstar/Iridium phone network, narrowband...

I immediately discarded the idea of a passive repeater. The link budget that the system works on probably makes this a non starter. You can calculate it if you like using two LOS paths joined to each other. (ie take the RX level of the first link and feed it into the 2nd and subtract about another 3dB)

I assume you have looked into and discarded running coax from the modem to antennas located at height. There will be major cable loss to consider at that frequency. You could of course use waveguide.

You are thus constrained to a same frequency repeater unless you can modify how your box works.

Same freq repeaters work provided you can get good isolation between the antenna systems. I havent done the link budget maths, but (for the downlink) placing an omni at height, connecting it to the input of a wideband preamp/amp design, running some cable length (say 20ft) to a directive (dish/gridpack) pointed down to your modem might do the trick. You only need enough total system gain to arrive at a similar signal level to what you'd get on your modem when it had an unobstructed sky view. It would be a good idea to use directive antenna(s) on your modem as well. You would do the same in reverse for the uplink (with a separate system) but keep in mind your amplifier has to handle a higher (input) signal level (but needs no difference in gain). There are probably brick amplifiers available from various manufacturers to do this, just having to pick the right frequency. I cant comment on the legality of this because I dont know. All the gain etc requirements should be pretty easy to calculate. What is most important is that the isolation "loss" of antenna placement must exceed that of the system gain, otherwise the amplifiers will take off (oscillate) and maybe cause major interference to not only your serverice but others as well.

I was involved in mine comms on 400MHz some time ago. The system we put together had two back to back yagis maybe 20ft apart, a cavity and a wideband amp arranged on both sides of the tunnel. (One was tuned to the handheld TX freq, the other to the RX). We didnt have legality problems because it didnt radiate outside the tunnel. The only real issue we had was heat as the amplifier ran class A!

I dont know whether all of this is worth the work. In fact I think that given Iridium/Globalstar uses a constellation of satellites the sky obstruction may not be a huge issue for you. I dont know enough about the density to make a judgement on this. I also noted (making a few web searches) that repeating system seems to be already available from Globalstar/Qualcomm themselves. I didnt look too deeply at it all...

Good luck!

Cheers Bob

> more radials.

Well, in theory yes, but in the real world , usually no. The reason
being the decoupling. Four or more radials will decouple the line
quite a bit better than two. I did tests adding radials to a VHF
ground plane, and I saw improvement with each addition of radials
I tried. Eight radials was a noticable improvement over four.
But I always put it down to the improved decoupling of the feedline,
rather than any big decrease in ground losses.
I imagine if you used separate decoupling sections to avoid feeder
radiation, the number of radials would matter little if any.
As far as elevated ground planes vs ground mount...Cecil does
have a point. It's common knowledge that a real low ground plane
generally sucks. You need many, many, more radials to equal
the ground loss of one at 1/2 wave up. While I don't doubt that
the low ground plane was beaten by the ground mount in Tom's test,
very few people actually run ground planes that low. If they do, they
can count on me to berate them for it.. IE: I often jumped on Cecil
for using one at appx 1/8 wave, and wondering why it didn't work too
well.
Thats too low, unless you have a lot of radials. In my observations
comparing ground planes, you really need to be at least 1/4 wave in
the air if you are going to use only four radials. Even then, thats not
optimum. At 1/4 wave up, 8-12 radials is closer to optimum. Four
radials at 1/4 wave is appx equal to about 60 on the ground.
By "optimum", I mean equals 120 radials on the ground...
Myself, I had a full length monopole on 40 m, with 32 ground radials.
It was rarely much better than my dipole on medium long paths of say
1500 miles. When I elevated the antenna to 1/4 wave, and used only
four radials, the performance was much better. Like day and night
really. So I agree, if you run an elevated GP, it needs to be up in the

air, or else you will need many radials. At 1/8 wave up, you need appx
60 radials to equal the 4 radials of the same antenna at 1/2 wave up.
I've heard many a tale of people running low band ground planes, real
low
to the ground, and having bad results. But you won't hear those bad
stories from the ones that run them at 1/4, 1/2 WL up.
MK

It appears that what I've been writing the past few days either isn't being read or isn't being believed. Among it is an explanation of why a "ground plane" doesn't produce an "image" of the vertical.

Since you appear to continue to believe this, please explain the mechanism by which you think a half wave disk produces an "image" of the vertical.

George Brown, the inventor of the ground plane antenna, found that only two radials were necessary. But when his company went to sell it, the marketing department decided that no one would buy a two-radial ground plane antenna in the belief that it would be omnidirectional. So they added two more to make it "look" more omnidirectional. The four-radial ground plane persists to this day.

Just a few weeks ago, I designed what amounted to a two-radial ground plane antenna as part of a consulting job. It was made from copper tape on a Duroid dielectric material, a lot like the window antenna John described. An omnidirectional pattern was a requirement, and I was concerned that either the flatness of the tape or the presence of the dielectric might have some impact on the circularity of the pattern. So I had it tested at a local lab. It was the most circular pattern they'd ever seen, having about 1 dB maximum difference between any two directions.

The disk forms an image by allowing the electric field lines to terminate perpendicular to the "mirror" surface on exactly the same lines as if they were heading toward a lower half of a dipole, while the radial currents in the "mirror" allow the magnetic field lines to encircle the monopole in the same pattern they would form if the missing half of the dipole were in position.

This same pattern of electric and magnetic fields above the "mirror" produces (half of the) photons that the full dipole would have produced. A half wave diameter disk is about the minimum size "mirror" that will keep the field patterns close enough to those of the dipole to launch those photons. A larger disk would do better, but not a lot better.

Did this antenna include any provision to prevent current on the
outside of the feed line?

Which direction did the feed line exit the antenna?

Hi John,

In fact a larger disk will actually raise the launch angle - hardly a
satisfactory mirror analogy.

>the "mirror" produces (half of the) photons that the

Photons? This is CecilBabble. Mirrors as "productive" sources of
photons demonstrates the failure of analogies.

That's not high enough Q Roy.

C'mon, I can only pass CW and PSK31 signals through mine without appreciable distortion.

Who needs to use SSB?

...

I did build one for 440MHz once though. Just a gap where the cap goes. It was one of the 2 ring types; about 1/2 inch spacing. and I could hit some repeaters with it... I could also hit some repeaters with one of those mini duckies too... not much to recommend the DDRR.

I think if you're raring to build a vertically polarized, fairly low profile antenna and you have a big supply of fat copper pipe and a high voltage, high current, all welded split stator cap, you could build yourself a fierce magloop.

Still have to retune every time you QSY... and I dunno... for similar construction quality and materials, how's the efficiency of the DDRR vs. the magloop? How low is the low radiation resistance of the DDRR?

No RF Current, as the cenbter conductor is "Floating"......
There maybe some voltage buildup , but it will not have current flow
untill the center conductor makes a circuit with something......

I don't know about Roy's antenna, but this subject has come up before,
and at the time I made a two meter vertical ground plane with only two
radials. No matter how I oriented the antenna, radially, I got the same
signal strength on my field-strength meter. And yes, I took precautions
to make sure the feedline wasn't radiating. (Many ferrite beads at
strategic places on the feedline to the point that feedline radiation
was undetectable.) If you can bring yourself to think in terms of
current directions and far field superposition of waves, this
behavior shouldn't be that hard to understand.

The theory behind the quarterwave vertical is the monopole above a ground plane, where the ground plane reflects the wave emitted by the vertical. The monopole is explained using image theory. In practice, the ground plane is replaced by radials. Do the radials reflect
the wave then?

The reflecting element on a Yagi manages to reflect most of the wave. The reflecting element on a Yagi is a parasitic element that has an impedance to cause the wave emitted by the driven element to flow in a particular direction. A Yagi normally has only one reflector. Although the reflector is in the near field of the Yagi, can a comparison be made with the radials of a quarterwave vertical antenna? The reflector on a Yagi is usually a thin tube with lots of air (gap) around it. Even though it occupies a small area, it still manages to reflect most of the wave. Yagi has a Front to Back ratio in dB.

Radials can be tuned. Some antennas have loading coils in the radials.

I notice that RF experts cannot agree on whether the radials reflect the wave or not.

Antenna theory is often about wires and metallic items reflecting waves, and the phase of the reflected wave. The phase of the reflected wave can be constructive or destructive, affecting the impedance of the antenna. If an antenna is mounted too close to the ground, the reflected wave cancels out the emitted wave.

Because a ground plane reflects the wave, the impedance of an antenna can vary with height.

Parastic elements on a Yagi have a mutual impedance to each other. Would you regard the radials on a quarterwave vertical as having a mutual impedance?

The radials increase the conductivity below the radiating element, decreasing ground losses. The radials are regarded as a finite or imperfect ground plane.

It's pretty easy to understand. Any two radials,
180 degrees apart and high enough, should theoretically
cancel each other's radiation in the far field.

The center conductor isn't entirely floating.

If the shield were closed at both ends, there would be no fields in the coax, but the coax center conductor at each end can have current induced on it from the outside world.

I think you'd go about describing the coupling as being via "fringing fields" at the ends if you were to think of a free end of coax with fields in it radiating into space, I'm thinking of the reciprocal behavior...

But this is a behavior where I'm imagining a differential-mode current existing to start with...

I think the answer is highly influenced by the exact details of the end of the coax and where it is with respect to other objects... the coupling is very light and mostly to the shield at each end... and I think this makes it not entirely unlike just putting the shield wire and the center conductor wire in parallel in space with the ends tied together.

I think current flows in the center conductor in phase with the current in the shield and there's very little differential mode current if any.

Certainly I'm wrong, I'm going to think on it some more and try to figure out how wrong...

What current flows in the center conductor if you short it to the shield with one wire at each end? What about if you do it with a solid metal cap ?

Do you deny the photonic nature of radio waves?

I just realized that the sentence you quoted s easily misinterpreted.
When I said "the "mirror" produces (half of the) photons that the
full dipole would have produced." I meant that half as many photons
are produced, compared to the full dipole antenna that produces the
same fields above the center line. I didn't mean that the mirror
produces half of the total photons that are radiated.

I agree. The point is, that I wonder if Roy's antenna feed had this
precaution that reduces the radiation effect of the feed line, or if
feed line radiation was part of the antenna.

From my EM311 days:

If I integrate the fields inside a short conducting cylinder, since there is no charge within the surface integral, there is no field within the cylinder.

So the volume integral, ?E.dL = 0 = No voltage. But, this isn't the case!

Now, if the cylinder is a 1/4 wavelength with distributed L and C ... ???

Since the cylinder is long compared to a wavelength, the distributed capacitance will couple a voltage to the inner conductor. The terminal impedance is open circuited [High Z] so no current flows.

Conclusion: a standing wave exists on the inner conductor. It is caused by the distributed capacitance and the magnitude of the standing wave on the cylinder.

Been away from EM for almost 50 years. I've probably forgotten too much.

==========

If they don't cancel-out each other in the near field then they don't
cancel-out each other in the far field either.

A pair of radials behave as a continuous dipole fed at its center via
a single wire. And it radiates.

A circular disk, diameter = 1/2 wavelength, fed at its centre
radiates.

But don't ask me what its radiation resistance is. It must be very
low.

ah, but it isn't! remember, 1/4 wave long (more or less) makes the open at
one end look like a short at the other end. there is also that distributed
capacitance all along the length between the inner side of the shield and
the center conductor... and also, the driving voltage at the ends are about
90 degrees out of phase, so there could be some non-trivial currents in the
center conductor.

>Do the radials reflect the wave then?

Hi Dave,

This has already been explained.

>The reflecting element on a Yagi manages to reflect most of the wave.

In fact, this is not true at all. Being a reflector is the name put
to the chosen effect, the cause of the effect is re-radiation, not
reflection. Reflection is merely the sum of phases that presents this
effect. One must design, by choice, the "reflector" to exhibit a
phase delay in its size, and in its distance from where the
"reflection" is perceived. Anywhere else and there is no reflection
whatever.

Trying to abstract the action of a yagi reflector to a radial has its
virtues, but explaining reflection is not one of them.

>I notice that RF experts cannot agree on whether the radials reflect the
>wave or not.

Dr. Johnson (about 1780) offers a comment to errors of perception:
"Johnson having argued for some time with a pertinacious
gentleman; his opponent, who had talked in a very puzzling manner,
happened to say,
'I don't understand you, Sir:'
upon which Johnson observed,
'Sir, I have found you an argument;
but I am not obliged to find you an understanding.'

>Antenna theory is often about wires and metallic items reflecting waves, and
>the phase of the reflected wave. The phase of the reflected wave can be
>constructive or destructive, affecting the impedance of the antenna. If an
>antenna is mounted too close to the ground, the reflected wave cancels out
>the emitted wave.

Um, yes. This catch-all combines many topics, but does not lead to a
single conclusion however. For instance, your last sentence lacks too
many qualifications to be true, and experience shows it is most
certainly false.

>Because a ground plane reflects the wave, the impedance of an antenna can
>vary with height.

Poor reading. A ground plane can completely absorb the wave, and the impedance of an antenna can vary with height. A ground plane can completely reflect the wave, and the impedance of an antenna can vary with height.

It seems that the common factor is change of impedance, not the quality of reflection. Unfortunately I will disprove this utterly, below.

The problem with your last statement is it separates "ground plane" from ground (height), and then recombines it to a separate conclusion (reflection) elsewhere in this posting. The radials of an antenna's "ground plane" is not the same ground plane of reflection so often employed in analogies.

>Parastic elements on a Yagi have a mutual impedance to each other. Would you
>regard the radials on a quarterwave vertical as having a mutual impedance?
>
>The radials increase the conductivity below the radiating element,

A paradox:
As all elements of an antenna radiate, and radials are part of an antenna, and radiating; then the more interesting question is how can radials be below the radiating element?

>decreasing ground losses. The radials are regarded as a finite or imperfect
>ground plane.

Much of these clippings from sources are disconnected from context; generally suitable only for a limited perspective; and often only for introduction to a fuller and more complete treatment. This is quite evident in their failure to support general conclusions.

>"Antenna Theory" by Professor Constantine Balanis. Second Edition p 165. A
>ground plane formed by a perfect conductor completely reflects the wave. If
>the ground is finite i.e. not as conductive, it still reflects the wave but
>not as well. The conductivity determines the quality of the reflection.

Not to dismiss Costa out of hand, but an extremely poor conductor, saltwater, reflects nearly 100% of the RF radiated towards it. Turning it into a sea of copper would hardly improve the quality of reflection. Again, poor context reduces information to garbage.

Let's consider this enigma further.

I have a standard quarterwave AM antenna that has 48 radials arranged around it above an average ground that is in fact better than I can find here in Seattle. At resonance it exhibits a characteristic Z of
Impedance = 36.15 - J 0.008024 ohms
its peak radiation angle is well above the horizon at 22ï¿½
if I were satisfied with 3dB poorer performance, I could depress that angle to 7ï¿½.

Now, to test this ground plane (the earth ground that is, because nothing in the radial plane is going to change here), I put this

antenna over poor ground (much like I would find in my back yard) and
we find at resonance it exhibits a characteristic Z of
Impedance = 33.62 - J 1.774 ohms
Hmm, nothing to cause the Dept. of Homeland Security to bump the white
house up from yellow alert.
The launch angle climbed to 26ï¿½, all of four degrees. If I were
satisfied with 3dB poorer performance, I could depress that angle to
9ï¿½.

Now, I put this antenna over good ground (much like I would find
floating in Puget Sound, just viewed out the window here) and we find
at resonance it exhibits a characteristic Z of
Impedance = 36.88 + J 7.924 ohms
Hmm, hardly different from average ground.
However, the launch angle dropped to 7ï¿½ and I can drop that to 1ï¿½ for
a 1dB (not 3dB) hit. Clearly the "ground plane" out beyond the
"radial plane" has made a substantial difference to the launch
performance (the combination of all phases at a distance) and for all
practical purposes absolutely no difference to its local operation at
the drive point.

So, with all respects to Costa, but your interpretation of his
clipping leaves much to be desired. Clearly seawater is a miserable
conductor compared to copper, and yet you would have to do a yeoman's
chore of work to build a radial field over average earth to compare
equally.

73's
Richard Clark, KB7QHC

p.s.
and just to be perverse, let's raise this out of Puget Sound, out into
outer space, well out of the way of the "ground plane" and discover,
yes, we lose 3dB gain. So this further compounds the folly of
platitudes that the ground plane, in regard to radials now, improves
launch performance.

Ok I am getting confused. You are saying that a groundplane will not work as good a a ground mounted vertical ? At what angle are you talking about? Are you more interested in working 500 miles or 6,000 miles?

Hi Pablo

I am curious about your globalstar instalation. What kind of antenna will
you use at the location that "sees" the satellites?
And, why is it *not* OK to use coax cable from the remote antenna to the
telephone in the shadows?

I am currently trying to build an antenna for Chris W. for his Globalstar
satelite phone.

Hi John,

This last question is standard CecilBaiting at which he is a master.

I've made a career in photonics, so you will have to go some distance
to start offering a case that comes remotely close to their cross
application. Barring that, why introduce concepts that don't advance
the topic? The following is hardly any clearer by clinging to poor
metaphors:

I guess the perceived quality of any given metaphor depends on your
mental model of the rest of the universe. Antennas and photons work
for me. If they don't work for you, I have no problem with that.

Remember, it is Cecil, not me, who demands agreement or eternal verbal
torture.

hi John,

It would seem that they "don't" work for you. I have no problem
shifting to a photonic dialog, but you have yet to emerge from a
rather muddy start.

>Remember, it is Cecil, not me, who demands agreement or eternal verbal

Hi John,

So, proceeding along your avowed lines of Photons, one of several
questions:
Presuming 100W radiated, how many photons would that be so that we
can talk about them by halves.

Yes, that is perhaps unfair, however it demonstrates how easily the
discussion can tumble for lack of quantifiables such as that original
offering of 100W.

Should we discuss how infinitesimal the energy is in a 40M photon?
(Easily accounts for why so many are needed for that same 100W.)

No, I suppose not.

Want to get into the problems of diffraction with object lenses that
measure less than a wavelength of the photon?

Hard to escape, and makes a mess of describing mirrors too, especially
when they are skeletal approximations as well.

I can offer more thread-busters when it comes to photonics, but that
is a slam dunk. Get us rolling on one ace proposition, and I will get
back to you in a couple of hours.

The real reason to use 4 radials or more is decoupling the feedline
shield.

Decoupling is very bad with two radials unless you get lucky with
feedline and/or mast length or use a decoupling aid like a common mode
choke.

On a commercial 47 Mhz GP I designed that had 4 radials, the radials
had to be isolated from the mounting and a ferrite decoupling sleeve
placed over the coax. I can't imagine how bad that problem would be
with only two radials.

Not true.

There is always an angle and direction where the fields do not fully cancel. The problem is the spatial distance is different unless exactly broadside to the pair.

Even 4 radials has this problem, but the more radials the less of an issue it is.

All you have to do is figure out how to decouple the feedline for less cost than the cost of three additional radials and a tiny easy to build choke.

Getting the feedline off a four radial GP is bad enough.

Not that it ever does any good to try to get you to think about what
you are saying, but that is nonsense Cecil.

The short doesn't affect CM currents. The 1/4 wl line can act as
current step up if the far end is grounded.

Also, reach back in your rear and pull out another impedance number.
The impedance value you grabbed from there is for a very thin wire
compared to length, like an end-fed HF antenna. Tubing is alot lower on
the end Cecil OM.

Before going off on another Cecil-knows-best event and destroying a
thread to make it all about you, run the model. Six meters, yagi,
tubing. Not 40 meters and #16 wire.

Well, you couldn't be radiating 100 watts in both cases if the field
strength is the same above the center line, but half the field is
missing in one of the cases.

But regardless of the radiating structure, if 100 watts at 40 M is
being radiated, you are launching about 2*10^28 photons per second.

> Yes, that is perhaps unfair, however it demonstrates how easily the
> discussion can tumble for lack of quantifiables such as that original
> offering of 100W.

Hence the stipulation that the field strength above the centerline
being constant, rather than the radiated power. I missed that we were
only talking about a case of radiating 100 watts.

> Should we discuss how infinitesimal the energy is in a 40M photon?
> (Easily accounts for why so many are needed for that same 100W.)

Not much to discuss. I don't do such calculations often, but I get
about 5*10^-27 joule per photon. What do you calculate their energy
to be?

> No, I suppose not.

Do you have some point?

> Want to get into the problems of diffraction with object lenses that
> measure less than a wavelength of the photon?

Sure. That will take us back to how an elevated radial system gives a
different vertical pattern than an actual ground plane or a lossy
ground does. You go first.

> Hard to escape, and makes a mess of describing mirrors too, especially
> when they are skeletal approximations as well.

You have to start understanding mirrors, somewhere. Perhaps you
prefer a different starting point. There are several.

> I can offer more thread-busters when it comes to photonics, but that
> is a slam dunk. Get us rolling on one ace proposition, and I will get

Hi to all

This is a related question to an earlier subject.

The ''help'' file of EZNEC says that ''The ground reflections which cause the low-angle pattern reflections take place farther from the antenna than most common radial ground systems extend, so ground radial systems have little or no effect on the ground reflection phenomenon.''

My question: Supposing that there are radiations coming from the antenna and going downwards (maybe at very steep angle), those rays could be reflected on the radial system and could add to the pattern, for any radial length...

The above sentence don't seems to validate such phenomenon.. So any further explanation would be welcome.

How much not true? I expect you're right, but you could make the
same argument that a two wire transmission line radiates because the
wires don't occupy exactly the same physical space. Reg made the
same point, but didn't provide any numbers, so, according to his
own philosophy he doesn't understand the problem.

Note the qualification "low-angle" in the sentence you quoted.
radiations going downward at a steep angle will be reflected off the
ground plane. I tried to explain this in my previous postings, but
apparently wasn't successful.

Roy, about the example from another subject, you (correctly)
illustrated that any radiation for an angle of 26 degrees or less will
be beyond the radial field

But what about an angle of say 35 deg below horizon? That ray would
bounce on the radial field, is'nt it?? That 35 deg is an example of a
''steep angle''

318. New Swiss antenna system...

Here is a very interesting article from SwissInfo.

A zeppelin will replace all of the terrestrial mobile phone antennas in Switzerland - if a Swiss inventor has his way.

Should Kamal Alavi's project for the high-tech airship take wing, the worlds of mobile telephony and data transmission would be turned on their heads.

Not only would the technology, called High Altitude Platform Systems (Haps), make the current 1,000 earth-bound antennas redundant, it would drastically reduce radiation.

A Swiss of Iranian extraction, Alavi is a former aerospace engineer turned entrepreneur who heads his own firm, Stratxx. Together with a team of 50 scientists, he is preparing a 2007 test run of the airship, which he has named the "X station".

Thanks to a GPS steering system developed by the Swiss Federal Institute of Technology, the 60-meter long helium-filled balloon will remain stationary at 21 kilometres above the earth.

A small-unmanned aircraft outfitted with a mobile phone antenna and other devices for transmitting digital data will be attached to the zeppelin. The X station has been equipped with giant propellers to help counter the almost constant buffeting from the wind.

Solar panels will supply the energy to propel the airplane and antenna. Underneath will be a platform containing technical equipment, conceived by Ruag, the large Swiss aerospace concern.

Radiation

"Transmitting on earth causes lots of radiation, because you have to penetrate countless buildings," Alavi says, arguing that phone connections are more reliable when transmitted from above because the signals are unobstructed by manmade or natural objects.

And "spot beam" antennas developed at Lausanne will allow radiation to be adjusted according to usage, regions with little activity receiving relatively less.

But Switzerland's largest mobile telephone operator, Swisscom believes not all of the technological hurdles have been overcome.

"This project cannot replace the present mobile telephone system," spokesman Sepp Huber told swissinfo.

The X station would not be limited to forwarding mobile telephone signals, but would also be capable of handling the radio, television and internet needs of entire nations.

Alavi believes that his project is also economical. He estimates that a Haps airship will cost no more than SFr40 million ($32 million).

In comparison, a single mobile phone antenna costs about SFr300,000 while a communications satellite starts at SFr600 million.

Alavi says the X stations are conceived to be low maintenance. In the event of a defect, the aircraft will be decoupled from the airship and returned to earth, much like a mini-space shuttle.

The project is now in a key phase. Solar cells are being tested at an altitude of 30 kilometres, and final preparations are underway for the launch of the first airship into the stratosphere. The entire system should be ready for testing a year from now.

The potential is enormous if Stratxx manages to be the first to fly with this new technology. About 20 Haps would be required to cover Europe alone while Africa would need twice as many.

swissinfo, Etienne Strebel

So, has anyone or group tried to get a couple ham antennas on this thing???

Funny, I don't see "fully cancel" anywhere in my posting.
I probably should have said "tend to cancel".

A free space vertical with horizontal radials in EZNEC
has horizontal radiation more than 40 dB down from the
vertical radiation. That's a high degree of cancellation.

Built a skeleton piece of giant coax in EZNEC, been playing with it as a monopole over MININEC ground.

I'm not going to claim much since it's probably wildly inapplicable, but I will claim that the answer to this question ain't trivial and depends on the details of the ends.

I find a current in the center conductor, It's very much bigger when the center conductor is slightly extended past the ends of the "shield" than when it's slightly inside. The shield is eight wires arranged in a regular octogon with the tops and bottoms tied together. It shows more or less normal fat monopole behavior when used alone. (33 foot element resonant around 6.4 MHz)

A fatter wire used for the center conductor has greater current than a thinner one. A very thin wire exhibits almost no current.

The peak current in the center conductor is about 3% of what's flowing in the shield for a 1 foot "diameter" (the circumscribed circle around the octagon) shield and a 6 inch diameter inner conductor. The current is very low at either end of the center conductor and peaks about 2/3 from the top.

This dumb model is full of holes of many kinds, I'm sure, but it does seem to show nontrivial effects of changing things a little bit near the ends of the coax (slight extension of center conductor outside of/retraction of center conductor into the shield)

I know this will shock regular group users, but he has taken things WAY out of context in the question above!

The actual problem is this:

A fellow placed a relay at the top of a half square antenna to change directions by switching from one flat top and drop wire to another. This is a VOLTAGE fed antenna at the ground. The vertical wires at the antenna ends have to be an electrical 1/4 wl long on the OUTSIDE for the system to work properly.

Cecil suggested he simply run the relay wires up inside a "shield" to the relay, and the shield would prevent the relay control wires from affecting the very high feed impedance at the base. The shield could be used as the actual vertical antenna lead.

Now I know to many people the problem is obvious. The problem is the IMPEDANCE of the open stub formed at the bottom of the vertical sleeve by the inner wire that has to go to a control system of some type and the outer sleeve.

That impedance has to be many ten's of kilo ohms so the shunting impedance is high compared to the impedance of the sleeve.

Full RF voltage of the feedpoint is also across the gap where the center wires leave the shield.

In order for the shield to have some meaningful effect on the system other than simply running the wires down in parallel with the fed wire, the impedance between the inner wire and shield must be VERY high at the bottom. It can of course be a SHORT at the top, since the relay just sits up there in the air with only the contacts making a connection, so the top is easy to handle with some bypass caps.

What Cecil totally misses is he formed what is in effect the electrical equivalent of a sleeve balun. The velocity factor of the transmission line forming this stub has to be the SAME as the outside of the sleeve so the INSIDE is 1/4 wl long electrical, and the the loss has to be very low. Otherwise the common mode impedance of the relay wires exiting the shield will not be several times higher than the antenna feed impedance, which is several k-ohms.

I've seen antenna manufacturers make the same mistake Cecil just made, and assume that running a cable down the center of a "hot" mast that is part of an antenna means the wires have zero current and zero effect since they are inside the shield, but anyone with any understanding of how the system works would catch the flaws in this idea right away.

The flaw is the differential IMPEDANCE between the shield and the shell forming an antenna has to be several times the common mode impedance of the shell or the system won't be worth a flip. Without that high impedance, the inner wire might as well just run down the outside of the sleeve and a couple good HV high impedance RF chokes be used to supply relay control voltage.

As a matter of fact at AM BC stations, when using two way or RPU antennas on the hot base insulated towers, I never bothered with running the cables INSIDE the tower. I went up 1/4 wl above the base, and bonded the cables to the tower. I spaced the cables a foot or so off the tower face on large insulators, so it formed an open 1/4 wl very low loss stub. This made the differential mode impedance of the open stub end at the ground very high, and allowed the cables to be brought away from the hot tower base without interacting a large amount with the tower base impedance.

This is a very simple common system that is often used in antennas (often in BC systems) , and once in a while used incorrectly by Hams and Ham antenna manufacturers (like Gap and MFJ and a few manufacturers of Ham log periodics).

Cecil will catch on with help I'm sure, I just don't have time to walk him through the problem step by step.

The issue is the horizontal opposing radials only have that degree of cancellation for perfectly horizontal directions.

You will be able to see your statement isn't true if you place the antenna in freespace and look at pattern distortion at various elevation angles. For example, the 2-d plot is skewed 2.11 dB from being circular at - 45 and +45 degrees elevation. The skewing gets worse at larger angles from the plane of the radials.

If the radials were REALLY radiating -40dB in all directions as you wrongly assume, there would NOT be significant FS change in the azimuth pattern at various elevations.

You looked at horizontal radiation, but the horizontal radials peak radiation is vertically polarized and nearly off the radial's ends. (Just like in a dipole pattern.)

The radials do indeed radiate enough to change the pattern a significant amount (but not at zero degrees), but the largest problem is decoupling the feedline shield. The fewer radials are used, the bigger the problem becomes.

There are VERY good reasons everyone settled on four radials, and it isn't the old wive's tale about making the antenna look good. Four radials is a reasonable compromise between excessive common mode problems and tolerable common mode feedline current problems, pattern, and cost.

Don't feel bad though Cecil. Many people miss this point, even card carrying Mensa members.

Cec,
Your use of the word "virtually" indicates a weakness in your ideas on
the subject.

The radiation, as small as it may be, is vertically polarised.

I have Antenna Model along with several implementations of NEC (both NEC2 and NEC4). Which modeling program I used depends upon the antenna and the type of installation I wish to model as each has its strong points.

Antenna Model uses the MININEC engine, however, it has been highly modified which removes many of MININEC's short comings. It is possible to model some antenna configurations that NEC has difficulty (and visa versa), for example, a Log periodic with a physical transmission line. Like most NEC implementations, Antenna Model allows the use the Sommerfeld ground model - something that other versions of MININEC do not, however, it will not model buried radials as can be done NEC4.

Antenna Model, like EZNEC, gives excellent customer support. Updates are free and good for life.

I find having both Antenna Model and NEC based programs gives me the option of choosing best program for the situation.

I don't think that is a "wive's tale".

From George Brown's (one of the co-inventors of the ground-plane)
book "and part of which I was" the following quote about the ground
plane antenna:

".... In our initial experiments we found that only two horizontal
rods (ground rods) functions just as well as four. Many people from
the Broadcast Sales organization came by to view our test and they
always expressed doubts as to the ability to radiate uniformity when
only two ground rods were used. To quiet them, we used four ground
rods for a while, thus stilling the criticism. When the antenna became
really popular, we did not dare confess to our ruse."

That doesn't seem to me to simulate a coax shield and
is more akin to parallel conductors. Doesn't skin effect
enter into the coax braid equation? It seems to me that
by floating the inside conductor and using the coax
braid as the radiator, we are forcing most of the current
into common mode on the outside of the shield. With zero
current at each end of the floating center conductor, why
would current flow on the inside of the braid?

I did not use the word "shield" or "sleeve". I said he could run
the control wires up inside a hollow 1/4WL radiator feeding the
rest of the half-square. Note that the two original antenna leads
were completely removed. The tubing becomes the radiator. Here's
the diagram of what I suggested where "RFC" is an RF choke with
RF bypass caps at A-B and C-D. FP is the half-square feedpoint.

```
FP 1/4 WL radiator 3/4WL
======================tubing=========================+---wire
A--RFC----------------------wire-----------------RFC--C--relay
B--RFC----------------------wire-----------------RFC--D--coil
======================tubing=========================
```

It is my contention that the RFCs located just inside the tubing at
both ends will prevent this configuration from acting like a stub
and that there will be little RF EM energy inside the tubing. How
many functional stubs has anyone seen with two RF chokes in the
conducting path?

> Now I know to many people the problem is obvious. The problem is the
> IMPEDANCE of the open stub formed at the bottom of the vertical sleeve

All DC circuits isolated by RF chokes inside the tubing and bypass
caps across points A-B and C-D.

> That impedance has to be many ten's of kilo ohms so the shunting

The impedance of the RF chokes is also pretty high.

Don't forget the RF chokes inside the tubing and bypass caps where
the wires enter and exit the tubing.

> The flaw is the differential IMPEDANCE between the shield and the shell

RF chokes at each end present a pretty high series impedance. The
RF current at each end is virtually zero and the wires are a non-
resonant length.

> As a matter of fact at AM BC stations, when using two way or RPU
> antennas on the hot base insulated towers, I never bothered with

We weren't talking about a tower. We were talking about solid tubing
made from copper or aluminum.

> Cecil will catch on with help I'm sure, I just don't have time to walk
> him through the problem step by step.

I'm willing to learn but you cannot simply assert something that
seems to violate the laws of physics and then say you don't have
time to explain it or furnish a reference. Please explain how a
stub can be functional with two RF chokes in the conductive path.

I know you have a bunch of followers who consider your word to be
gospel and depend upon nothing except faith for their belief in you,
but I am not one of them.

Modeling such an arrangement gave no real noticeable difference
between using three or four radials.

That's what I thought. Sometimes, orders of magnitude are
important. Otherwise, people would be worrying about the fact that
they're closer to the center of the Earth in the middle of the
bottom of a flat bottomed hole than they are at the edges.

I reran my EZNEC coax model with a cage with an octagon loop every foot in height... This is a pretty good shield at 40m, I think. The holes are .002x.007 wavelength.

The difference is apparent.

Not much confidence that this is modeling the problem... but maybe it's better:

Ran it with wire inside/outside the shield. Did #2 wire this time to simulate thin wire down the center of a pipe. Before, the inside/outside comparison yielded almost identical results. Now it doesn't...

Wire 6 inches outside shield:

Wire No. 26:
Segment Conn Magnitude (A.) Phase (Deg.)
1 Open .00356 86.70
2 .00776 95.54
3 .01039 103.14
4 .01208 109.03
5 .01323 117.85
6 .01373 126.69
7 .01297 133.85
8 .01159 144.14
9 Open .00684 154.69

Wire centered in shield:

Wire No. 26:
Segment Conn Magnitude (A.) Phase (Deg.)
1 Open .00201 53.19
2 .00298 65.98
3 .00324 71.00
4 .00509 45.58
5 .00387 78.85
6 .00401 118.35
7 .00308 63.54
8 .00347 137.70
9 Open .00503 164.46

Anyway, the point that the original cage was a bad model is taken. An additional approximation toward a full shield changes things a great deal.

Should anyone want to take a look: http://www.n3ox.net/cage_coax.ez

Oh, the laws of physics don't preclude RF from getting in the ends of a piece of coax, by the way.

There is no minimum cutoff frequency for the TEM mode in coaxial waveguide.

There is in hollow waveguide with no center conductor.

You still need to be able to couple to the ends, and a floating center conductor is not the best way to couple energy in. However, there's no fundamental physical reason why currents *won't* flow on the center conductor in an open-ended piece of coax.

Dan

Message-ID: <h0rco3-rti.ln1@p400bob.personal.cox.net>
Source record: 56538

Hi Chas

No doubt I will be mentioning stuff you have already tried and tested...

I assume you mean QRN rather than QRM?

- It is probably worthwhile seeking out the source of the noise. Such things as turning house equipment off and listening etc. I have horrendous QRN here (Longview East Texas) from power line noise. It is worse of course on HF but it does interfere with weak signal work on 2m. The noise dissappears during and about an hour after rain... I have already done a walkaround with the 2m SSB RX to determine where the source is (pole hardware near a oil pump about 200 yards away) but havent contacted the power company yet. (Keep in mind that by law they are obliged to fix it. The FCC apparently helps a lot here. Your MARS status will probably make a big difference as well)

- Most radios are very good at reducing pulse noise like from a car ignition. My oldish Kenwood radio also does a credible job on the PLI at the expense of some selectivity. It may be worthwhile having a play with the noise blanker circuit to also suppress noise with a slower rise time (like PLI). You may also want to try using a separate sense antenna and amplifier into the NB circuit. If your blanker isnt affecting the noise you may need to increase its sensitivity. (make it adjustable though!)

- If you are message handling only, a digital mode (like Olivia, PSK etc) will go a long way to getting the signal through. Useless of course if you are phone/radio patching families..

- Yes I agree, try another RX to see if the S/N is any better. If it is then the first radio might have some problems.

- Elsewhere on this group you will have seen a discussion on noise reduction techniques using antennas. I wont repeat it here. I am sure you know the vertical is "noisiest" and a pure horizontal dipole is "quietest". Perhaps the inverted V construction is responding to the local noise more than a straight horizontal antenna. Using a separate low antenna (often a magloop) for RX can also yield much better S/N than using a highly placed one. Since noise level generally on HF is much higher than the RX sensitivity this can work very well. It isnt a viable solution (say) from 10M and up through VHF/UHF

- External DSP might be viable. You can get software nowadays that will take the radio's audio output and "wash it". It is much better to use the IF for DSP but PC soundcards can only sample at 44kHz or so. I havent dabbled in this much but for Windows have a look at http://www.qsl.net/dl4yhf/spectra1.html and see if it helps. Of course

your PC power supply etc may then cause a problem!

- If you have one noise source that looks like a point source radiator (ie not power lines) phase cancellation techniques might work. ie using a second antenna and a passive phase delay circuit tune for max s/n by adding the noise to itself 180 degrees out of phase.

- Your feed system might be responding to signal. I dont know the antenna design you mentioned but unbalanced "balanced feeder" tends to radiate as well as receive and since it is vertical will respond to noise. A balun is the supposed trick here but I am sure others will jump on this often contentious topic.

Like I first mentioned try to find the location of the noise source. If it is some power lines or a known location put up your windom such that a nul is pointing in the noise source direction or at least not parallel to power lines.

Hope this helps

Cheers Bob W5/VK2YQA East Texas

There is no significant FS change according to EZNEC.

> radiation is vertically polarized and nearly off the radial's ends.
> (Just like in a dipole pattern.)

Unfortunately for that argument, the radiating currents in
a dipole are in phase, i.e. designed for maximum radiation. The
radiating currents in symmetrical radials are 180 degrees
out of phase, i.e. designed for minimum radiation.

A watt is a joule per second. The formula gives the number of photons per second that carry a watt (or a joule per second) once you provide the Hz (frequency).

By the way, I am having second thoughts as to whether or not there should be a 2*pi factor in there, since most physics formulas deal with frequency in radians per second, not cycles per second. But the photon energy formulas usually deal with wavelength, and I have never seen one that assumes a wavelength is a radian of a cycle, rather that a full cycle, so, perhaps Hz is the correct unit.

If anyone can clear this up for me, I would appreciate it.

Dear JC,

You don't need software. What you describe is non-existent anyway. What you want is a long experienced antenna designer who can be permanently engaged on your behalf. There are very few of such creatures about.

You will have to be numerically quite specific about particular problems. And even then you will get solutions which, with luck, are probably only in the right ball-park.

On the other hand, ball-park solutions are perfectly satisfactory. In the nature of events, no-one has ever solved an antenna problem which is other than in a ball-park. Fortunately, antennas work quite well even when in the wrong ball-park.

Download a free copy of EZNEC and in a few months time you may have solved your first complicated, specific problem. As time goes on, you will become more adept and there will be no need to engage a long experienced antenna designer. You will have become one youself and can offer your services for hire.

If you have a specific problem you may, if you are lucky, find a computer program written by someone who has already solved it. But its highly unlikely to be exactly the same problem. It will be in a somewhat different ball-park.

Optimisation is out! You will have to contend with whatever you can get your hands on. What's been done before. Take it or leave it!

Reg.

I should add that sticking the wire even a little bit (six inches) out the ends of the skeleton shield increases the current on the center conductor...

I expect that the situation with a long wire exiting the bottom will couple MUCH more energy into the center conductor.

So, in the context of control wires up an antenna element, the wires coming away from the antenna and a load to represent a choke should be included.

I'd also like to refine the shield mesh but I ran out of segments !

Dan

Hi John,

Closer to 4.63 ï¿½ 10^-27 joule. Not enough difference to matter. So,
we are talking about a little more than 10^28 photons and when we
return to your statement (or is it twice that?)
>>>I didn't mean that the mirror produces half of the total photons that are radiated.
or
>>> I meant that half as many photons are produced, compared to the
>>>full dipole antenna that produces the same fields above the center line.

I have to again exclaim:

>> No, I suppose not.

Further, as to your "stipulation:"
>>> the field strength above the centerline
>>>being constant, rather than the radiated power. I missed that we were
>>>only talking about a case of radiating 100 watts.

It would be strange to talk about radiation without some expression of
power to the antenna. 100 watts has been a cardinal value in this
group for many years. Field strength is generally expressed in
volts/meter. Somehow, its translation into eV to follow the photon
metaphor seems rather strained. Going further with this convolution
of centerline partition that relates to same fields (same?) to explain
a difference is also quite odd. Would you care to elaborate on this
concept of the centerline?

>Do you have some point?

This is odder yet, you introduce the topic and ask me what my point
is? My own separate observation is the introduction of photonics
doesn't add much does it?

>> Hard to escape, and makes a mess of describing mirrors too, especially
>> when they are skeletal approximations as well.
>
>You have to start understanding mirrors, somewhere. Perhaps you
>prefer a different starting point. There are several.

Starting with radials would seem to be in keeping with the thread.
Shifting starts when you haven't finished seems to defeat the
progression of where you were going.

>> I can offer more thread-busters when it comes to photonics, but that
>> is a slam dunk. Get us rolling on one ace proposition, and I will get
>> back to you in a couple of hours.
>
>I have no idea what you are saying with these two sentences.

No doubt. I read these same admissions with some frequency. It
rarely keeps me up at nights worrying anymore.

You were going to tie this all together weren't you?

Of course it didn't. That's the point I was making. The number of
radials, from 1 to N, is immaterial.

As N increases there will be a slight improvement in radiating
efficiency. The N loss resistances are all in parallel as seen by the
feedline.

Hi John,

That would be 2 pi radians per second as frequency - same thing as a
cycle. For photonic interactions the classic treatment is usually
with wavenumber as frequency not cycles nor radians. However, the 2
pi difference is the difference between the Planck constant
represented as h, and its rational equivalent (with 2 pi divided out)
of h-bar.

Hello, and as long as kudos are being handed out I thought I'd jump in and say that while programs like EZNEC add some user-friendliness and graphical capability they rely on the NEC (usually NEC-2) engine. For NEC-1, NEC-2 and NEC-4 Gerald Burke and others at the Lawrence Livermore Lab deserve a lion's share of credit for drafting user documentation, correcting bugs and enhancing code that was originally done in the early '70s by MBAssociates for the U.S. Naval Research Laboratory (NRL). Just a bit of NEC history. Sincerely, and 73s from N4GGO,

John Wood (Code 5550) e-mail: wood@itd.nrl.navy.mil

We are talking about what happens at the short on the left,
not what happens at points A or B where the coax is connected.
W8JI said the short doesn't affect the common mode current.
Seems to me, the short has approximately the same effect on
common mode currents as does a link coupling.

The coax center conductor is connected at 'A' and the braid
is connected at 'B'. Do you agree with W8JI that the common
mode current at 'X' must equal the common mode current at 'B'?

Guess it depends upon one's definition of "immaterial".
One horizontal radial will certainly radiate more
horizontal radiation than two opposing horizontal radials.

The center line I am referring to is the mirror line of the ground
plane or radial group that allows a monopole to have a field pattern
(both E and H) above that mirror line, that would exist there, if the
antenna was a symmetrical dipole. Without the mirror effect, the
field pattern of the monopole depends on the path the feed line takes
away from the monopole, and any other conductive objects nearby.

Since I am talking about field patterns, it seemed natural to switch
from total radiated watts to field intensities and the photons that
field emits and where those photons head.

>>Do you have some point?

I see that you snipped the line of nonsense you originally posted that
prompted this question. You asked,

"Should we discuss how infinitesimal the energy is in a 40M photon?
(Easily accounts for why so many are needed for that same 100W.)

No, I suppose not. "

So I asked if asking a question and dismissing it made some point.

> This is odder yet, you introduce the topic and ask me what my point
> is? My own separate observation is the introduction of photonics
> doesn't add much does it?

While amateurs may ultimately be interested in radiating power in
particular directions, we are discussing the physics of the radiation
process, and photonics is one way to think about that process.

>>>Hard to escape, and makes a mess of describing mirrors too, especially

> progression of where you were going.

The ultimate radial pattern is a solid disk. Once you understand what
that does to the field pattern, you can start toward a radial wire
layer, and see how, in important ways, like the ability to carry
radial current, it resembles a disk. Then, you can explore how
reducing the number of radials alters the approximation.

>>>I can offer more thread-busters when it comes to photonics, but that

Thanks for help, I think I wrongly explained my problem, here is the question:
1/ I design an antenna, for instance a 3 el 20m beam.
2/ I enter into EZNEC wires dimensions, spacing, height, source.....
3/ EZNEC calculates gain, F/B, SWR....and results are acceptable.
4/ Now let's suppose my objectives are max F/B as I have a QRM source opposed to my favourite transmitting direction and SWR< 1.5 on a given frequency range as my transceiver is very SWR sensitive and I can't use an antenna tuner.
I accept changing wire lengths and spacing but not boom length.
Is there a way to have EZNEC, or another software, doing automatic iterations until it reaches the best F/B-SWR compromise ?

K6STI's Yagi Optimizer 7.0 does a very nice job of this. You can
choose the weighting of Gain, F/R, SWR or Impedance and optimize over
any choice of frequencies. See my results for a pair of stacked KLM
Yagis on 28 MHz here:

http://users.vnet.net/btippett/yagi_optimizer_7_0.htm

Unfortunately K6STI no longer markets his software to hams (due to
software piracy issues). Hopefully you can find someone with a copy
who can optimize your initial results.

>
> Ron

Nope. I think the elevated ground plane is superior to the
ground mount as long as it's high enough in the air to avoid
excess ground loss. As far as long haul, there may not be
too large a difference if each system is equal as far as ground
loss. IE: a ground mount with 120 radials, and a GP at 1/2 wave
high with 4 radials should show about the same efficiency. So
for long haul dx, they should be fairly close in theory. But...
You have a better ground/space wave with the elevated antenna.
This can come in handy when talking 50-100 miles away when
the band doesn't support NVIS with a dipole, etc..
When you run the elevated antenna, you must always think of
height in terms of wavelength, not feet or meters. A 2 meter GP
can be fairly low, and still very efficient. But not a low band GP.
A half wave is a different height on each band. Being I recommend
a minimum of 1/4 wave height when using only 4 radials, that
can be pretty high on a lower frequency. On 40m, I ran one at
36 ft at the base of the radiator. Thats just over 1/4 wave up.
If I ran the same antenna on 80m, I would have to mount it at
72 ft to have the same efficiency. About 145 ft on 160m.
Soooo...If you can't go that high, you must increase the number
of radials to lower the ground losses to a equal number.
If you have a ground mount with 120 radials, you need about 60 radials
if the antenna is at 1/8 wave. About 8-12 radials if the antenna is at
1/4 wave. About 3-4 radials if the antenna is at 1/2 wave. All these
have the same appx ground losses. So you can see, if you run a 80m
ground plane at 15 ft, the ground losses will be high unless you use
a whole lot of radials. So in that case, it's really more practical to
use the ground mount unless you don't mind all that wire in the air.
But equal loss ground mount vs ground plane? I'd take the ground
plane anyday... I ran one on 40m and it kicked serious butt on
long haul dx. And yes, I use the verticals on the low bands for
mostly long haul. I use dipoles, etc for NVIS.

A simple question.

Are you hearing QRM, [M]anmade interference, heterodynes, whistles, etc?

Or, are you hearing lots of static QRN? [N]atural noise sources?

One of the basic principles of the cellular telephone system is that the same parts of the spectrum can be used by many phones at once. This is possible only because each cell covers only a limited area. High spots which cover huge areas are pretty common -- just look at typical repeater or TV/FM broadcasting locations. But you won't find cell phone installations there except in very sparsely populated areas, and for very good reason -- there simply isn't anywhere near enough spectrum space available to accommodate all the users within range.

Figuring out how to cram a couple of orders of magnitude more users into the same already-packed and efficiently used spectrum must be one of those "technological hurdles" yet to be overcome.

But in the meantime, I'm sure Alavi is living quite well off the money from the naive investors which never seem to be in short supply.

I think it's just a matter of degree. The more RF chokes there are,
the less current will flow.

It would be a straightforward matter to add more wire to the model and
include loads for bypass caps and chokes.

In either case (wire inside or outside of the shield) good decoupling
where the wire lead exits is going to be important. The model so far
may suggest that being inside the shield is better than being
outside... but without that lead trailing away from the antenna some
distance, it's not time to conclude much about the relay+half square
problem.

The 40m coax monopole answer would seem to be "yes, there's current on
the center conductor, but it's small and coupled in through the ends"

If you're using the standard EZNEC, you're going to have to knock
another section off the top of the cage... if you've got EZNEC+ then
just add away...

I may try it when I get home... knock another section off and try a
control wire...

Might have to send off my money to Roy and go for EZNEC+... I know I
can get around segment limitations with other programs but I do like
EZNEC. This is probably the ninth time since I got the program a few
months ago that I've hit the segment limit ... i like meshing things...

Gives me a question about the (EZ)NEC limitations... should I be
watching out for fine 2D meshes? It seems to work OK in this case...
the base impedance of the meshed monopole and the current distribution
viewed on the segments all makes sense, and it seems to me that there's
not much reason to doubt that the currents are calculated correctly in
the mesh as long as it's not coarse with respect to a wavelength... any
caveats in this regard?

73,
Dan

Instantaneous sum of the common mode currents at B (you can give it an overall minus sign if you want, but it's right for common mode):

Current flowing toward B from X + Current flowing toward B from Y - current flowing out from B via coax shield - current flowing out from B via coax center conductor.

All the common mode current on the coax will flow on the outside. So current flowing out from B via coax center conductor is zero.

So current flowing on the coax braid = Current flowing from X to B + Current flowing from Y to B.

Points A and B are one point except for the reactance of the short connecting them.

Cecil,

You put great faith in passing you Mensa exam.

With that in mind, what possible difference does the shield make once the inner conductor is bypassed and choked at each end?

In case you can't understand, the answer is NO difference.

Without the chokes and bypasses, your idea won't work. With the chokes and bypasses, the idea isn't needed. The relay wire can run right down the mast with no ill effects.

It's so basic and simple, even a Mensa member can follow it!

This is such a common basic circuit used in so many BC applications I
can't believe people are modeling it!

Clue:

Draw it on paper. Draw a vertical conductor running up along an
insulated base tower and attached at the top. Now feed the tower.

How do you get the wire away from the tower at the bottom without
shorting the insulator? Two ways:

1.) You form a 1/4 wl shorted stub with the wire, attaching it to the
tower 1/4 wl away from the tower base, but spacing it away from the
tower from that point downwards, either inside or outside the tower. In
this case the dielectric has to be very good (like air) and the
diameter of the tower has to be large compared to the wire if the wire
is inside the tower. This is so the base inpedance open circuit
impedance is very high compared to tower feed impedance.

or another method:

2.) You simply use RF chokes at the bottom. In this case the wire can
be inside or outside the tower, and it can be secured directly to the
tower.

Let's see if we can make something so basic and simple so complicated
it takes 1000 posts.

Since the Ham asking the original question HAD to have the relay 1/4 wl
above the open end, the ONLY choice for dielectric when the wire was
run INSIDE a closed conductor was air. It had to be an electrical 1/4
wl long, and had to be a very low loss stub since the antenna was
voltage fed (high impedance).

The suggestion of enclosing the wire in a shield was useless in that application.

I should have said "the more RF chokes there are, the less current will flow in the center conductor of the case where the wire is inside the shield" by the way.

If the RF chokes and wire are inside the shield, it will keep the current off the wire inside the shield.

However, where the wire exits the shield, currents can still be induced on it... this is what allows current to flow on the unchoked center conductor, right? So why wouldn't it flow in the other direction.

So you need chokes some distance outside the shield to isolate the rest of the wire from the antenna.

If you put the wire outside the shield and put chokes at the top and bottom, some distance away from the antenna, then a very large current will be induced on the wire between the chokes compared to the current you get on the wire inside the shield. However, this doesn't immediately translate into more current on the control wire trailing away. It is just saying something about the wire between the top and bottom chokes.

What you're trying to do is decouple the control wire going away from the antenna from the antenna. Decoupling the control wire that runs up inside or outside of the antenna isn't very important as long as current doesn't flow on the control wire to the shack.

Whether or not inside or outside of the tower/tube helps depends on a lot of factors and should be answered with some sort of calculation...

Seems that the various claims are testable...

I'll post anything I come up with.

Dan

389. Re: Quarterwave vertical with radials

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-11 19:14:16 UTC
From: David <nospam@nospam>
Message-ID: <34ydnZdtyundZy7ZnZ2dnUVZ8qKdnZ2d@bt.com>
Source record: 56428

One of the earlier postings suggested that the quarterwave vertical antenna with radials was elementary and easy to understand. I have never found this antenna easy to understand.

RF experts on this newsgroup cannot agree on whether i) the radials reflect the wave or ii) the field from the radials cancels out. The standard academic books show that the principle behind the vertical ground plane antenna is that the vertical radiating element emits the wave, and is reflected by the ground plane.

You can view a conductor as having current pushed through it by a RF source, or the current can be induced in the conductor by the wave. This is a boundary condition in Maxwell's equations, referred to in theory of transmission lines and guided waves.

You can view the radials as reflecting the wave and having current induced in them, or they can have current pushed through them by the RF source. This is probably the same thing, due to the arrangement of all antenna parts forming the antenna impedance. In image theory, the impedance comes from both the self impedance and the mutual impedance.

It appears that a single counterpoise wire is connected to the RF ground side to provide a conductor for that side and be a form of dipole. If a proper RF ground is not provided, the result may be RF in the shack e.g. the RF tries to return via mains wiring. Does connecting several wires make the RF ground side less live i.e. occupying a larger area to be more of a reflector and thus dissipative? If a RF ground is live, it can be dangerous to touch it. Do you increase the area of RF ground to make it less dangerous to touch e.g. radials under a carpet when relatives and pets are about?

```

As you probably know, standing waves in distributed
networks modify the conditions. The current "flowing"
from X to B may not be the same amplitude or phase at
X and B. The current "flowing" from Y to B may not be
the same amplitude or phase at Y and B. This is NOT
a DC circuit! So how can any sane person claim that
the common mode current at X is identical to the
common mode current at B?

I modeled the original question Cecil asked on r.r.a.a. (current on a coax center conductor of a monopole made of coax) because I was curious and because my wetware simulation for the amount of RF coupled into the end of a piece of coaxial cable wasn't up to the task. I didn't start with the eHam question in mind.

I don't know offhand how much the coupling between the center conductor and shield is at the ends of the coax, so I tried some stuff with the only electromagnetic code I have lying around my house.

The relay question is not very interesting, it's just an engineering one.. throw good chokes at it. Done. I agree.

I wanted to know what the current was in the center conductor of a piece of RG-8 being used as a monopole. The answer to that question is not trivially calculable, though it might be trivial in the sense of being trivia... who cares? I did.

We're talking about the instantaneous common mode current of the real system. That's the current actually flowing in the same direction in both legs of the stub.

This member of MENSA is having difficulty in parsing
your statement. What does, "you Mensa exam", actually
mean? Does the pronoun, "you", address the Mensa exam?
Wouldn't it be better to address the Mensa exam as an
"it" rather than as a person? Your numerous deviations from
the accepted laws of physics and accepted English language
construction have me confused.

> With that in mind, what possible difference does the shield make once
> the inner conductor is bypassed and choked at each end?

What I said is that, contrary to your strange assertions, is that
the RF chokes and RF bypass capacitors block the stub function
upon which your entire argument rests. The result of my suggestion
is *NOT* a stub function as you have so stubbornly insisted. So I
ask you once again: Please prove that a stub with two RF chokes in
the conductive path is actually functional as a stub. If you cannot,
your entire argument falls apart.

Let us see what would be involved if you had EZNEC and had to do everything else yourself the hard way. You already have a crude, satisfactory design for 3 elements, wire lengths, wire diameters, spacing, height, etc.

Only the boom length and presumably wire diameters and height are fixed and you wish to optimise everything else for maximum F/B ratio and minimum SWR.

Everything else comprises : 3 lengths and 1 spacing. This makes a total of 4 independent variables.

You now vary the first variable over a range of say 4 increments, keeping all the other variables constant and keeping a record of the 4 results of F/B ratio and SWR

You then vary the second variable over a range of 4 increments, keeping all the other variables constant and keeping a record of the results.

You continue to do this until you have done all possible combinations of the 4 variables. You will have a 4-dimension array of results of F/B ratio and SWR, making a total of 512 observations.

Now search the observations until you can find the maximum of F/B ratio combined with minimum of SWR

If it looks as though the minimum SWR or the maximum F/B ratio lies outside the 4-dimensional array then shift the variables in an appropriate direction and repeat the whole procedure until a max and min are found.

The trouble with modelling programs is you have to enter element lengths and spacing via the keyboard. It would be nice to have a program to do it for you. I am unfamiliar with the situation. Such a program might exist - one which outputs F/B ratio and SWR.

Reg.

But standing waves of common mode current can
and probably do exist.

The amplitude of the common mode current varies
depending upon its location in the distributed
network. At a common mode standing wave node, the
common mode current may measure zero. 1/4WL away, it
may measure an appreciable magnitude. I have
measured such on my own transmission lines.

I suspect a dead short forces a common mode
standing wave node. What else could possibly
happen?

Run the test again more carefully. You are looking at something wrong.

Perhaps you didn't look at the entire azimuth plot at 45 degrees
elevation.

There is a large skew with a 1/4 wl vertical over two 1/4 wl radials,
and it gets worse at higher elevation numbers.

Seems that neither one of you guys realize that common
mode current standing waves usually exist so the standing
wave common mode current amplitude is NOT constant from
one point to another in a distributed network. The lumped
constant model strikes (out) once again. When are you guys
going to realize that RF is NOT DC?

As mentioned in another posting, YO (Yagi Optimizer) would be a good bet. Strange that piracy caused the author to quit offering it completely; seems like any sales are better than none, and not selling a program only makes piracy more likely, not less.

But check out the EZNEC co-pilot program from Dan Maguire, AC6LA, at http://www.ac6la.com/. That page lists several of his offerings; it's MultiNEC that you'll be most interested in. Though it may not completely automate the optimization, it should make the process much easier and faster for you.

Cheers,
Tom

Who said anything about two radials? I am reporting
the standard model with four radials. I was away
from my computer for four days over the holidays
and may have missed the two radial discussion, if
there was one.

The radial radiation cancellation that I earlier
described was based on four radials, certainly
not on two.

As I just posted in another followup, MultiNEC (add-on for EZNec and other NEC programs) takes care of just this sort of thing for you, and takes much of the tedium out of the process. As an Excel spreadsheet, it does require that you have Excel on the computer you're using.

Cheers,
Tom

Why? The documentation says:

```
**************************************************************************
This software is copyrighted. It has been provided to
you on the condition that you will not sell, rent, lend, give
away, or otherwise transfer the software to others.
**************************************************************************
```

As I read it, there is no problem if I use it to optimize a model
for someone else. I'm NOT volunteering to do that however.

In the case where the J-pole is isolated (crossbanding HT at the feedpoint?) there's absolutely a node for the common mode current at the short, just like there's a node for the current on a wire at the end where the current can't flow.

If you put a feedline on it, though, the standing wave pattern of common mode current changes.

The feedline + jpole develops some pattern of standing waves on it. The common mode current is induced on the entire length of coax and stub...

The sum of the common mode currents at point B is always as stated before... but the magnitude of ALL THREE of them depends on the details of the coax, whether or not there is a choke balun on it, the length and boundary condition on the other end of the coax.

That is to say the common mode impedance at the top of the stub where the halfwave is connected depends on the details of the feedline.

Stub vs. Stub + Coax: different common mode standing wave pattern, different common mode impedance at the top of the stub, different magnitude of current induced on the stub+coax than on the plain stub...

Dan

On my diagram, the coax is always connected
at A and B so *nothing has changed*. I just don't see
any reason for the common mode current at 'X' to be
exactly the same as the common mode current at 'B'.
Do you?

Whilst the above comments are very well made I must say that there are some good ideas with this whole HAP thing. A lot of my lecturers and professors are involved with a big chunk of the research into this venture, and for high speed broadband data access the idea is good. The points made about cellular systems are true, but it is my understanding that in densely populated areas there would be more HAPs up in the air, each could have multiple cells potentially...

Having said that I do get the impression from some research seminars I've been to on the subject, that there is still a lot of work to be done before the proposal can be realised to it's full potential, but I do think the principle is sound.

> Do you?

No, but no one said that except you. I would guess this is another typical diversion by you, where you try to change what others say when you put your foot into doo doo.

What I said was:

1.) Current was the SAME at both sides of X.
2.) Because Y is NOT terminated, the CM current unblances that line.
3.) The length of the line from the short to X transforms this CM current t a new value.
4.) That value can be considerably higher than the CM current at X.
5.) When people tap a coaxial line up on the stub, they now create additional CM problems besides the initial one. The new problem is the initial imbalance in the stub can be aggrivated by imbalance where the coax transitions to the stub.

The whole system is a mess. The ONLY way it models good is if:

1.) The center point of the stub is floated from ground.
2.) The coax is decoupled through a high common mode impedance on its shield at the connection point t the stub

When people through a source out on that stub, it looks like coax through a perfect balun. At the same time they float the stub shortyed end, and that makes the stub DECREASE CM current along its length.

In the REAL world the center point of the stub is almost always grounded. In the REAL world the coax is never perfectly decoupled.

This is why all the models of J-poles are generally wrong. Only models that include the shield connection and the grounding or connectiong of

the shorted end of the J, when properly done, are correct.

Cecil, you really do need to think about things like this much more careful than you do before telling others they are using DC models. It just makes it look like you can't think clearly about very simple basic systems when you miss the points I listed above.

Dear Ron:

Go for a good, well made, USA LPDA. As an example: the Tennadyne T10 (www.tennadyne.com) compared to the OB9-5 has a longer boom, uses more material, has a lower cost, has no custom/duty issues, and a long track record.

The gain figures posted by Tennadyne are reasonable and well labeled. For MARS like service, an LPDA can not be matched.

If you decide on a LPDA, contact me off-line and I can provide some simple ideas on simplifying installation.

From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <_I2dnY1R5aeGqSnZRVnygg@bt.com>
Source record: 56459

If ground loss is very small when ground resistivity is very low (sea water) and is also very small when resistivity is very high (arid deep desert sand) then ground loss must be a maximum at some intermediate value of ground resistivity.

Does the ground loss reach its maximum when ground resistivity is around 377 ohms (Conductivity = 2.65 milli-siemens).

Now where have I seen 377 before?

It's just hard luck if your back yard happens to be about that value.

Reg.

I absolutely and enthusiastically second that. My contribution has been almost solely an interface (although at around 60,000 lines of code it's not completely trivial). The underlying code was the work of a number of very savvy people, including Dr. Burke who still supports it as time permits. EZNEC would not have been possible without those people's extensive, painstaking, and superbly documented work.

Many other people have given a good deal of time in aiding with the development of EZNEC. I encourage all EZNEC users to read the "Acknowledgements" section in the "Introduction" chapter of the EZNEC manual.

Reg Edwards wrote:
> Why on Earth anybody zips up software these days I can't imagine.

I thought you'd have a better imagination than that, Reg.

o To reduce the size of the transferred file.
o To package a set of files together, e.g. documentation and sample
files along with a program, or a set of related programs.
o To secure it; it may not be very robust security but would
discourage
the casual user.

For the present example, though, the benefit is marginal at best.

Cheers,
Tom

>
> No, but no one said that except you.
> What I said was:

Sorry, that's not what you said. What you said was that there is
as much common mode current flowing down the feedline (at point B)
as is flowing into the half-wave end-fed section of the antenna
(at point X).

```
+--A--------X-------------------
|
+--B--------Y
```

The half-wave end-fed antenna starts at point X. The feedline is
at point B. Here's what you said:

Hi John,

This is still rather obscure. You are not talking about a line, but
yet another plane. World of difference there, but I won't dispute
semantics further.

Simply raise that monopole, complete with radial plane and the center
line (as you call it), ABOVE the ground plane. I've already analyzed
this elsewhere in conventional jargon, but here it seems Photons offer
a different conclusion. Unfortunately you aren't prepared to pursue
this as you admit later.

The conventional analysis is perfectly capable of dealing with feed
lines or by avoiding them altogether. One can certainly conspire to
fail and corrupt the analysis, so avoiding distractions and placing
the source in the model, at the feedpoint, removes a lot of
uncertainty.

>Since I am talking about field patterns, it seemed natural to switch
>from total radiated watts to field intensities and the photons that
>field emits and where those photons head.

Photons (as any radiation in this case) are incoherent and radiate in
all directions.

>While amateurs may ultimately be interested in radiating power in
>particular directions, we are discussing the physics of the radiation
>process, and photonics is one way to think about that process.

I am perfectly content and competent to that goal.

>The ultimate radial pattern is a solid disk. Once you understand what
>that does to the field pattern, you can start toward a radial wire
>layer, and see how, in important ways, like the ability to carry

>reducing the number of radials alters the approximation.

I don't see a photon in this at all.

>> You were going to tie this all together weren't you?
>
>Probably not, since I am working through the process in my own mind.
>I am not the teacher so much as a student trying to learn something
>useful. I hope my posts generate more useful discussion from others
>than I have gotten from you, so far.

I have, with neutral objectivity, posed issues of diffraction. For one, the quarterwave antenna, in close proximity to a quarterwave mirror (those radials), does not present the characteristics of a point source that might render attractive solutions. Further, even a point source ray striking a quarterwave mirror suffers considerably.

The long and short of it is that Photons make for an interesting discussion with regards to antennas. Unfortunately, and as you obliquely observe about me writing for myself, it seems I'm the only one willing to carry the topic.

Roy fails to mention that he recently discovered a bug in the NEC code
which he passed on to Gerald Burke at LLB. I suggest that Roy is also
envolved more than just providing an interface for running the NEC
engine.

Two radials do indeed cancel each other's radiation to a large
extent. But I certainly didn't say there were two and only two
radials in the entire system. I missed four days of postings.

Hi Dan,

All the issues you focus on are quite particular and specific, and
perhaps too much so. I find them equally interesting and you ask
reasonable questions. Unfortunately, you question above suffers from
every problem imaginable for measuring, and any report you get without
considerable qualification is probably sheer fancy. It suffers from a
version of Heisenberg's problem of disturbing what you attempt to
measure, and invalidating everything in the process.

Another way of stating this problem, with more practicality, is that
you have to put a wire into the coax to add your meter to make the
measurement. This then brings that wire's own contribution, which, as
you've noted, can raise the stakes considerably.

I, too, have played with a variant of your model (I can push the mesh
finer and have worked with a 16 sided coax model). However, instead
of driving the line like a monopole, I simply plunked a source into
the wire skeleton of the "shield."

But to return to your own published model, I've played with the length
of wire 26 after discovering it emerged from both ends of the coax. I
don't put much credit to Cecil's invention of topics, so I am unaware
if this wire length meets some criteria (even if it did, I would still
suspect the detail would have been spurious). Be that as it may.
After truncating the wire 26 so that it did not come anywhere closer
to the mouth of the coax (either end) than 5 feet, "induced" currents
plummeted like a rock.

< snip >

Which prompts me to ask a question: If a quarterwave vertical antenna has many radials only a few feet above the ground, and these radials could be made progressively longer and longer, does the antenna eventually fail to "know" where the ground is? How long is "very long" to bring this about (if it happens)?

I kicked some numbers around. By the formula two times antenna_length-squared divided by wavelength [2D^2/lambda], I make the far-field distance for a 14 MHz quarterwave vertical be only 2.5 meters [less than a quarter wavelength] ... but typical radials are already longer than that, aren't they? So this isn't a near-field/far-field boundary issue, is it?

Is it possible that these are BPL emissions from a local power line?

Or is it possibly just a bad insulator. If it goes away in the rain, a bad insulator is the probable cause.

Richard, You hit this nail on the head, for sure:

> All the issues you focus on are quite particular and specific, and
> perhaps too much so. I find them equally interesting and you ask
> reasonable questions. Unfortunately, you question above suffers from
> every problem imaginable for measuring, and any report you get without
> considerable qualification is probably sheer fancy. It suffers from a
> version of Heisenberg's problem of disturbing what you attempt to
> measure, and invalidating everything in the process.

I don't have much trouble with the antennas I actually build. The aluminum and wire I sling around tend to behave.

I do have some vested interest in overspecific modeling in the sense that since I'm deploying all my antennas from the balcony of my apartment (with its overhanging roof), and don't have much space to build, adjustments and pruning are very hard to do. Some performance gains can certainly be had by adjustment... but in my situation now it's so much easier to push bits around in EZNEC.

This one, though, was just pure impractical theoretical curiosity. That, and a little bit of being concerned that people seemed to "know" the answer, that the answer was obvious, and, well, I didn't think it was. The current in real experiment would be, as you pointed out, pretty much impossible to measure without disturbing it.

But as I see it, from a practical standpoint, in a real system where you're using the shield of a piece of coax as an antenna , the current in the center conductor never matters.

The existence of the current matters, at least as a learning experience. It matters in the sense that some seem to think that there couldn't be a current, just because a piece of coax is "shielded". Or because the center conductor is "floating". It's precisely the fact that the center conductor is "floating" that makes the (probably) weak coupling at the ends important.

Thanks for posting your results. What you describe certainly jives with the fuzzy idea that I've got of what's doing the coupling ... or at least where it's happening. Of course, the tube without center conductor is certainly a waveguide well below cutoff, so we've got solid footing saying a short wire inside a long conductive tube a small fraction of a wavelength in diameter will have little current on it... and the model also exhibits this.

I'm done with this one unless I find a leadless current meter (small, battery powered with an A/D converter and optical fiber out?) and a

big piece of copper pipe laying around!

73,
Dan

> MMANA does what you want and it's free.

However, note that because MMANA being a MiniNec based program, when using none vertical elements below 0.2 wavelengths accuracy rapidly drops. If you'd like to optimize on (lower) HF, a Nec based program is prefered

Furthermore, I don't think optimization is out. But, if it should be so, it still will learn you very much about the effect of antenna dimension changing on antenna performance.

And last but not least, because of being freeware, experimenting with MMANA or 4nec2
[http://home.ict.nl/~arivoors/] will cost you nothing (besides a little studying), weather you would like to use a traditional optimizer of a genetic algorithm based optimizer.

Arie.

Cecil,

In your alleged system, you carried RF through the coax and used the coax as a swixcthing stub.

In the other fellows system, he had a high impedance feed and had to get a relay conductor past the high impedance feed without affecting the system.

They are TOTALLY different.

Even a card carrying mensa member can't be that out of touch with a simple system like this.

73 Tom

I think the electronics problems are trivial compared with the matter
of maintaining the platform at altitude and geosynchronous.

There is not much air for a lighter than air ship to float in at that
altitude. A quick estimate of 21km is about 65,000 feet. It would seem
to me that a platform that could hover at that altitude keeping pace
with the earths rotation could also circumnavigate the earth in 24
hours in the direction of the rotation.

The energy required to maintain that hover is going to be substantial.
Forget filling the Zep with Hydrogen. Even if you can devise a scheme
to fill an evelope with nothing (vacuum) It is going to be monstrous
in size to displace a hundred kilo's or so.

Count me out on the project...

Hello all experts and gurus,

I am experimenting with a 18m (54tf) end fed slooping (30 degr) wire. The "bottom" end is located right at the waterfront and is also the feedpoint. (Automatic tuner.) I will use 16 radials ea 10m/30ft where 8 vill be in freshwater and the other burried in my lawn. I choose this length of antenna in order not to have a voltage/high impedance feedpoint on any the bands 160-6 which I will use.

A fullblown vertical would of course be a better option but the slooping comes from the only available convinient atatchment point. I am also very restricted as far as "construction work" goes. The id&#65533;a is to have a "stealth" simple multiband antenna. Preliminary work mainly on lowbands gives good results for non DX work.

So... does anyone of you gentlemen and women (?) have any experience/thoughts/id&#65533;as of this concept?

Thanks in advance.

SM0FKI /Ulf

You seem to be confused by my actual system in my yard
Vs the hypothetical piece of coax I introduced as a
simplified example for discussion purposes.

Forget the coax example. In my yard, I have run two wires
up a piece of 1/4WL aluminum tubing to a relay which
switched a top hat in and out just as the other fellow
wanted to switch a wire in and out. The only thing that
I would have to add to turn that system into switchable
half-squares, like the other fellow has, would be two
3/4WL runs of wire. I suspect the SGC-230 autotuner at
the base would match the new feedpoint impedance just fine.
I've never seen an impedance it couldn't match.

> In the other fellows system, he had a high impedance feed and had to
> get a relay conductor past the high impedance feed without affecting
> the system.

The two physical configurations being discussed are *identical*,
being 1/4WL of tubing through which two DC wires are routed.

> They are TOTALLY different.

Once again, you make an outrageous exclusive statement
completely divorced from reality. If any one thing about
the two antennas is not different, your statement is
completely false. One wonders what compels you to make
such strange assertions.

I don't have any real experience with such an antenna, also not sure what you mean by sloping 30 deg. Is that 30 zenith, or elevation?

Given a zenith angle of 30 degrees, the height will be about 47 ft and the end displaced by 27 ft from the ground plane center. Models for such an antenna indicate an input impedance of 14 - j 1982 ohms at 1.8 MHz. With such a structure the input voltage at the base feedpoint will be 5.8 kV RMS, with 100 W input. I have often considered such an antenna, but have never gotten around to actually putting it up.

Regards,

Frank (VE6CB)

Typical, as usual I goofed. Changing the segmentation and not
correcting for the feedpoint segment. The input impedance is
in fact 5.467 - j 876.482, for an input voltage of 3.75 kV RMS,
with 100 W applied. Corrected code below:

You've missed the point Roy made. Adding connections (more HAPs) does
not add more bandwidth. Those extra HAPs will be competing for the
same (now diminishing by proportion) spectrum.

>Having said that I do get the impression from some research seminars
>I've been to on the subject, that there is still a lot of work to be
>done before the proposal can be realised to it's full potential, but I
>do think the principle is sound.

When there's existing hardware (after all, no one is telling the
consumers to throw away their phones and buy HAP versions), and
Hindenberg technology is a century old; then any proviso "there is
still a lot of work to be done" translates into SEND MORE MONEY - a
message tape with an infinite loop.

Ask researcher1: "can I float a balloon?"
researcher1: "Sure, no problem."

Ask researcher2: "can I transmit and receive from a height?"
researcher2: "Sure, no problem."

Ask researcher3: "can I find a stabilizing platform?"
researcher3: "Sure, no problem."

Ask researcher4: "can more connections serve more customers?"
researcher4: "Sure, no problem."

The sum is not equal to the whole:
Ask customers: "can you still hear me?"
customers: "What the ****! My line is dead."

Hi Bill,

Strange as it may seem, yes you would be in violation.

Copyright is the author's total monopoly to insure his revenue from
his creation. If you disrupt that revenue flow you are breaking the
law. You said it yourself, he doesn't market to amateurs - rather
professionals who will pay for the LICENSE to use it professionally.
If they choose to do someone a favor, and drop their fee, that is
their hit, not his. He granted them the right, by LICENSE and at a
cost, to lose money if they wish.

Hence the irony meter being pegged.

Is this lawyertwist's interpretation?
Like it is not COPYright it is REVENUEright?
Don't you anybody ask to read my copyrighted magazine issue! You will disrupt the revenue flow of the publisher/authors. Oh, and don't read any magazines in your dentist's office while you are shaking for the treatment. You could be imprisoned, but Sandy Burglar can give disks to Chinese and stuff his pants with classified documents with impunity.
If I paid for the software/book and I use it 24 hours a day or once a year is not anybody's freakin business. Copyright is about COPYING or selling unauthorized copies. Gimme a break, or yuoze guyze just love to argue phantom threads?

Get on the air. Tesla Radioclub fired up from it's new QTH as N2T celebrating 150th birthday of this greatest engineering genius (who would be turned into idiot by this NG gurushiip).

Jerry,

For the location that actually sees the satellites the antenna must be an omnidirectional one ('cause globalstar constelation is LEO), perhaps the one that comes with the GSP-1620 (check http://www.globalstarusa.com/en/data/data_display.php?id=6). Since the OEM modem will be on the ground and since I cannot use any coax cable between them, I'm trying to find a wireless alternative, i.e. place an omnidirectional antenna over the highest obstacule and forward/repeat that RF signal down thru a directive antenna back to the ground where another (to be build) directive antenna (to avoid multipath satellite fixes) is attached to the modem. My question is about how to build such forwarding/repeating RF device and the corresponding directive antenna for both ends.

Regards,
Pablo

Thanks Frank, 30 degrees is the slanting angle ref to ground. The azimuth is not important for this discussion.
I would appreciate if you could do the same calculation for 3.75 MHz. This would help me estimate my ground losses based on the SWR measurements I have done. On this freq the SWR is at a minimum with a SWR 1.2 reading.

Regards

SM0FKI / Ulf

Did that save even one life? If the Titanic's CW operator
had not bullied the California's CW operator off the air,
the California might have saved the day. But after such
shabby treatment from the Titanic's arrogant CW operator,
the California's CW operator shut down and turned in.

We aren't talking about failure to receive a CW SOS. Those ships that
responded did so after receiving word of the sinking by radio. They
saved many lives from the lifeboats which would otherwise have been lost
to the cold.

Hi Pablo

The site you referanced implies that there is only one antenna supplied
with this Globalstar GSP1620. Your text indicated that the GSP 1620 sends
and receives signals on two widely seperated frequencies (1.62 GHz ans 2.4
GHz).
Although I would like to know more about how the GSP 1620 works, this is
probably not the right place for me to get educated.
I'll be impresed if you manage to make dual frequency system work by using
radiated RF to connect between a remote location and the Antenna.
If there was any posibility that the entire Modum *and* Antenna could be
located up at the location where the satellites can see it, you could
(maybe) create a RF link between the GSP 1620 Modum and the remote location.

That's correct, there's only one antenna that handles both frequencies.
In the bottom of the antenna you have two SMA connectors, one for TX
and other for RX. In case you are further interested in this modem and
its capabilities you can download the integrator's manual from
http://common.globalstar.com/doc/common/en/products/gsp1620_integrator_manual.pdf

Well I certanly do hope to get around this problem, since I cannot
place both the modem and antenna in the same higher spot.

Regards,
Pablo

The STUB is a balanced transmission line. If you quoted the entire post
everyone would see what I meant.

Your constant little games of pulling things from context just waste
time and ruin the purpose of technical forums. You really should quit
that, and try to use the forums for education.

C'mon Cecil, you've been licensed as long as I have. I Know you Know CW. Does that mean we're virtually obsolete?

RE Titanic:

The same result would have happened. The ship hit an iceberg in poor visibility. I don't think icebergs carry GPS transponders these days.

Now, the Titanic's GPS; does it have transponder capability? The older GPS units do not. Anyway, after the crew slipped by the iceberg that ripped it open, the radio op gets on the air and reports "SOS" or equivalent. The nearest ships respond. Under conditions similar to 1914{?} the Titanic still sinks. Many people still die. But, now we know to 20 feet exactly where the ship was when it sank.

GPS won't make a difference. Neither will CW today.

I still enjoy CW.

Hi Richard,

1. I paid for the non-professional version of K6STI's software while he
WAS selling to amateurs. If you read his agreement carefully, it only
prohibits transfer of the software itself.

2. I am not sure Brian markets YO to professionals any longer. There
was apparently one well-known antenna manufacturer who bought his

non-professional version and used it to design commercial antennas. I understand that this contributed to Brian's decision to exit the amateur business, but the main reason was someone in Europe hacked his RITTY program and posted it publicly.

3. If I were to do a gratis optimization for someone today, that would not violate the original license (i.e. transfer of the software itself) and Brian's revenue flow is not being broken since he no longer has any revenue flow from it. If a professional consultant were involved, they would have to show they sustained actual damages (i.e. lost business) which might be difficult to prove (not to mention the time and cost of doing so).

> Hence the irony meter being pegged.

No, that's the too-much-time-on-their-hands troll meter pegging. :-)

It's a shame the piracy issue drove K6STI from the ham business. He is truly a genius and I love his AO, YO and DSP Blaster programs. I believe he's now doing something in the audiophile business...their gain and our loss.

73, Bill W4ZV.

Hi Bill,

This is NOT a defense against infringement. The author's rights are total, and the author's monopoly is total. There is nothing in the law that suspends those rights or monopoly even in the event of death of the author, so being out of the market place is a specious argument.

This, and everything else you've had to offer may in fact be done, I see folks run red lights frequently too.

>If you read his agreement carefully, it only
>prohibits transfer of the software itself.

I've read many agreements, but not this one. If you have a means to render it faithfully here, then perhaps so; otherwise those others I've read inform me better.

There are two additional issues here.

First, a registered copyright is valid for 55 years, it transcends death and becomes part of the copyright holder's estate. It can be renewed under specified conditions. So, going out of or changing business does not void the copyright. By law, the legal penalties begin at $100,000 per violation.

Second, the principle of REASONABLE USAGE is applicable to copyrighted material. Example: I buy a Copyrighted CD for my personal usage. I am allowed to install an additional copy on my computer for my personal usage. I am allowed to install an additional copy on my MP3 player for my personal usage. All subject to the condition that only one copy will be used at any one time. This does not violate the copyright law and applicable precedents.

Libraries are allowed to makes partial copies of copyrighted material. It is the REASONABLE PRESUMPTION that libraries provide data. Universities can make partial copies of copyrighted material for academic classroom and research

usage. Etc.

The legal burden for proof of REASONABLE USAGE rests with the individual or institution who purchases the license.

>
> Regards
>
> SM0FKI / Ulf

Ok Ulf, No problem. I may have misunderstood what you meant by the angle of your antenna. I took it to mean 30 degrees from the vertical (Zenith) angle.
For my model I assumed the radial system was 0.1 ft (3.05 cm) above an average
ground. The above ground radial system model approximates a buried radial system,
although NEC 4 does allow below ground radials. Neither NEC 2 or NEC 4 allows radials directly on the ground. Also the finite ground Sommerfeld/Norton
method will not support two ground parameters. At best my models are only an approximation of your antenna, but will hopefully give you some idea of what
to expect.

On 3.75 MHz NEC 2 indicates an input Z of 26.8 - j 174.1 ohms for an input voltage of 340.5 V RMS with 100 W.

Hope this helps. If by chance I have misinterpreted the exact antenna configuration
just let me know, and I will be glad to run the models again.

You are welcome to e-mail me directly, just remove the "nospam" from my address.

Regards,

Frank

Hi Pablo

By my standards, you have a problem that would be Very impractical to solve. You cant use coax from the antenna (located at the higher spot) to the modem. And you cant locate the modem at the higher spot, with the antenna.
I would go so far as to state that there is No solution to your problem. If I had the obligation to demonstrate to you that the "higher spot" antenna idea wont work with your restrictions, I'd start with basic far field path loss.
But, if you absolutely have to get that Globalstar GSP1620 working, I hope I'm wrong.

I agree Roy. The **software** is licensed...not its output. Brian's
license agreement says absolutely nothing about output.

Am I correct about Brian going into the audio business? Thought you
might know.

not sure if i am really correctly describing a idea that came into my mind properly and hey it may be a 1/2 baked idea but i was trying to think of what might be a interesting experiment to take advantage of some unusual 'realestate'

my building complex consists of several equal height and almost equially spaced buildings from one end to the other would be a few blocks long at least over 500ft n/s and going west about 1000ft (more like a t shape east is a big park (3000ackers)

i was wondering if i could make a quad or somthing that each building would have a piece of

thinking would eliminate the boom and i would end up with a antenna that might be very interesting on say 40 80 160 (&others) maybe i am wrong and end up w/marginal gain/performance

anythoughts as to someone that might have constructed a simular experiment, if it might yeild me 'good gain'

the idea of a quad arose, because i was thinking it'd offer more performance than say a really long dipole, w/the quad or so i could have many elements

the idea of a beam came to mind too but i thought making many horizontal parts and interconnecting them may be harder

the smallest 'gap' between buildings seems about 50ft

any thoughts?

Back to antenna optimization, modeling software is a great tool and can save a lot of tinkering with hardware in the freezing nights, but has to be taken with a grain of salt. I treat it as a "bring me into the ballpark" tool, rather than "gospel".

K6STI did great job with his YO and AO and W4ZV used it to optimize his KLM stacks very closely.

I tried it on my 3 el. Quad design, which was originally designed on the 2m antenna test range and then scaled to HF bands, which worked quite well, within 50 kHz in resonant frequencies. When I tried to make it better by sticking it into optimization software, the software made it better, on paper. When I readjusted the dimensions accordingly, thing was off and worse than before. Maybe software did not capture the color of spreaders. There are still some parameters that modeling does not capture 100% and I am always taking the modeling results with grain of salt.

There is whole "industry" of antenna "designers" doing it on models and proclaiming as gospel. Reality is sometimes cruel and doesn't care what the model says, especially when considering the environment in which antennas are to operate. Just caution not believe 100% blindly what the model says, as we saw in case of loading coils. I love the free space designs :-)

YO, AO, MMANA, 4NEC2 are great tools and to see how good they are, just let them optimize the same design and see how close they get within each other.

Sorry to see Brian, K6STI quit producing ham stuff, but I do not blame him. I was in the similar situation, developed Cyrillic languages support for desktop publishing, sold few dozen copies, only to find that there were hundreds if not thousands in use from Praha to Vladivostok. I can see my stamp in the fonts files all over the world. So I quit producing the software and let the Microsoft carry on, now it is built into Windoze.

Well, searching the documemtation of version 6.04, I can find only this in YO.DOC

Copyright 1995 by Brian Beezley, K6STI
All Rights Reserved

Version 5.0 is not quite the same, this is from READ.ME, nothing in YO.DOC, or any other file

Copyright and License

This software is copyrighted. It is licensed for use by
the purchaser only. Copies may not be sold, rented, leased,
loaned, given away, or otherwise distributed. This copy is
licensed for amateur use only.

That's all there is in either version of YO that contains the "copyright" in any form, case insensitive. I am ignoring the companion programs. Interestingly, the .EXE files do not include a copyright notice internal to the program, at least in plain text. The only thing that shows when running the program (v6.x) is "Copyright 1995 by Brian Beezley, K6STI All Rights Reserved" at the top line on the files menu. I am writing the last from memory since it's a DOS program, so I might not have it perfect.

Under current U.S. law, a copyright notice isn't required in order to secure a copyright; the copyright automatically exists as soon as the work is created. Adding a copyright notice does bring some advantages if a lawsuit is filed, however.

Hi Tom,

Pretty unsophisticated, certainly. This redoubles my experience with
other licensing as being far more exclusive.

However, with five patents of my own, I can certainly attest that
these scraps offer protection that have all the muscle of paper. These
ego certificates allow you to get past a lawyer's secretary and spend
money trying to convince judges with the technically savvy of
troglodytes.

Franklin was right about these matters.

As for automated optimization, NASA spent huge bucks on this stuff to
design twisted paper clips to replace Walt's work of 30 years ago. I
can well bet that license runs pages. If the testimonials to Beezley
are any indicator, the utility of the software is in inverse
proportion to the length of its license.

The person would not die on my watch, as long as I could get a signal out
and someone on the other end could copy it. I'd probably have to practice
a bit to get back up over 50wpm, but I can do 25 or 30 all day long.

However some of it does work very well. YO, when used correctly can just barely beat K1FO's designs, which were done on a PDP11, using a special version of BASIC, as I remember from conversations with him long ago.

He got the designs as right as possible, using an EME'rs version of right. He hit max gain for boomlength within less than 1dB, pattern is wonderful, SWR BW is astonishing, and pattern and gain are all fairly constant across the usable SWR BW. Input impedance is not too low, at about 20-25 ohms, and efficient match can be had with a T-match. And it handles ice and rain detuning perfectly. Build sensitivity is nice; you can skew the design by induced errors of +-2mm element length and +-5mm vertical off the boom and +-2mm element position on the boom with no significant change. Gain not off by .1dB, pattern not off by 2dB, normally less. I ran a lot of tests. And I could be misremembering a bit, but probably by too high rather than too low.

And YO could beat K1FO by only hudredths of a dB. If he'd had more CPU power to do more runs per day...

Hi Tom,

This is all pretty significant stuff. Its success probably ties in
with what Reggie had to say about the quality of automated software
being tied to the competence of the user/designer (Reggie may wish to
distance himself from my paraphrase however).

As a negative example, some half decade or more ago we had a fractal
designer who threw as much computational horsepower at this as his
budget would allow in hiring eager, bright faced graduates building
parallel processors. They perhaps knew Genetic Algorithms (the hot
topic in academia whose bloom had long faded in cut-throat industry),
but certainly nothing about the bajillion degrees of freedom in
antenna design. Well, that stack of computers was more a marketing
paper weight than a design producer - I've never seen an independent
headline announcing the dawn of a new age of fractals in Boston. In
fact, it would seem that same NASA program stole their thunder - and
it is still a yawn.

Dear Roy and the group:

As you know, my other job is that of a patent attorney. It is time to comment.

We are not concerned with patents. It is common to overlap patent protection of something useful with copyright protection of an expression. This is more common when software is involved because a patent might involve software and Congress has made it clear that software is amiable of copyright protection.

As you have observed, a copyright notice is no longer required. However, I always tell clients to provide such a notice. Judges, most reasonably, may wonder why a notice was not provided when to do so costs (in most cases) nothing and the absence of a notice can cause mischief. The requirement not to require notices was due to pressure from European interests.

If one thinks one will need to defend one's copyright, it is beneficial to register the copyright with the Copyright Office (part of the Library of Congress) - a simple process.

Let us turn to what copyright is: it is the right to prevent the making of copies of a work by others. One who holds a copyright to a work has the right to control copies of that work. Congress and the courts have carved out some exceptions. We have seen one used here where one copies small sections of a copyrighted book or paper. Researchers and universities are given some narrow rights to copy the works of others. In a law suit, an important aspect is the degree that someone's unauthorized copying has actually injured the copyright owner.

Absent a specific contract to the contrary, one who legally purchases a copyrighted work may sell it, destroy it, read it if it can be read, and run it on a computer if it is software. Such a lawful copy may be used to facilitate the crafting of another work (such as using WordPerfect to write a letter) or may be used to facilitate the fabrication of useful articles (such as the use of EZNEC to design an antenna that is improved in some way).

Let us keep patent protection and copyright protection in their separate cages.

To the issue of the French radio amateur who started this long string (and with a nod to the opinion of the experienced radio amateur in the UK): optimization of more than simple antennas still requires the intersession of a thoughtful and experienced human. My experience has been that the human's main contribution relates to crafting an adaptive notion of what optimum is,

for the subject antenna. In other words: knowing when further playing is
not appropriate.

That is a complete quote of your item number 1. What you said is
self explanatory. You said the current flowing onto the antenna
is equal to the current flowing down the feedline. You were wrong.

Mac, I am not sure of you meaning of a "specific contract".

It is often the case that we acquire software (being a copyright work)
under a licence that is an agreement between the licensor and the
licensee.

The agreement may be in the form of a general license, for instance an
end user licence that the user is deemed to have accepted in using the
software, or it could be in the form of a specific formal agreement
executed by the parties.

That agreement may limit the licensee's rights, including the purpose
for which software is used.

I give an example, the BestOne mainframe performance evaluation suite
licence limited it use to execution a specific computer and explicitly
only for analysis of performance data collected from that computer.

Isn't the license agreement like any contract in that the parties can
agree to anything lawful.

It seems to me that one has to read the relevant licence agreement to
form a view on what is or isn't permitted by the licence in addition
to any rights under copyright statutes.

From: ferrymanr <richardferryman@btinternet.com>
Message-ID: <NvydnSIpffgHsSvZRVnyvQ@bt.com>
Source record: 56357

My brother was recently kind enough to bring me back an Autek RF-1 analyser.
Unfortunately the manual got left behind. Most of the operation is
intuitive and there are some notes on Autek's web site but no downloadable
manual. So far this little box is proving to be very effective and
useful - a lot easier to carry around than the MFJ.
Does anyone have a manual they can scan for me?
Thanks from Richard (Dick) G4BBH

Since The radio operator of the Titanic knew exactly where they were,
GPS would have made absolutely no difference. If radio hadn't
existed, everyone aboard would have died.

Tom Ring wrote:
>
> And YO could beat K1FO by only hudredths of a dB. If he'd had more CPU
> power to do more runs per day...

YO7 includes a model of K1FO's 40 element 70 cm Yagi. In YO7, it
measures:

Gain 20.93
F/R 24.01
Z 21.8 + j5.4
SWR 1.0
Gain FOM -0.4 (versus theoretical limit for a given boom length)

In <10k iterations (minutes on a 250 MHz Pentium II), YO7 produced:

21.24
19.54
20.9 + j46.1
1.0
0.0 (I stopped it when it reached this)

You can tweak for Gain, F/R, etc depending on how you weight
performance tradeoffs. Looking at the current distribution, it appears
fewer elements might result in a better design. YO7 does not optimize
for number of elements but it doesn't take much effort to remove
elements and see what happens on the same boom length.

Regarding K1FO's design using Basic on a PDP11, here's Brian's
description:

****
YO includes an automatic optimizer that can maximize
forward gain and input resistance, and minimize backlobes,
sidelobes, and SWR. The optimizer iteratively adjusts element
lengths and spacings to optimize performance objectives you
specify using parameter tradeoffs you decide. It can perform
both local and global optimization.

YO is calibrated to NEC, the reference-accuracy
Numerical Electromagnetics Code from the Lawrence Livermore
National Laboratory. YO and NEC results normally differ by less
than 0.05 dB in forward gain, a dB or two in F/B, and a couple
ohms in input impedance. You can invoke NEC from within YO to
verify results.

YO's analysis and graphics engines use assembly language
with pipelined floating-point code optimized for Pentium processors.
****

The entire yo.exe program is only 82k (and DSP Blaster is only 16k).
The major change from YO6 to YO7 was the addition of global
optimization, so it will not get stalled on local maxima.

The other thing I must give Brian credit for is his excellent command
of English. I have *never* seen a spelling or grammatical error in any
of his documentation, which is very unusual these days.

Oh, I give Brian lots of credit. He did a fantastic job. And there were times his developments happened at a blistering pace.

I've had more than a little experience with YO and AO. I was an alpha tester for him. I once ran an optimization for 3 weeks straight in AO. Unfortunately it was a dead end design idea for an odd dual band yagi. I digress.

When I said you could only get hundredths of a dB, I meant it. I did hundreds of models and thousands of runs trying. You are probably not optimizing to the specs that an EME'r would desire. Setting the tradeoffs in YO to get the balance right is touchy, and changes as boom length increases. You also need to partially or completely turn off optimization on a few elements for it to do its best job on a long yagi.

The K1FO yagi designs are still the best around in my opinion. For one reason above the fact that they have great specs - they are a very high performance design that is easy to reproduce. And when in an array they do not detune as much as "better" designs.

I am not so sure about that. My first and only experience with Onstar - was not a very good impression. The "phone system" didn't dial out for crap - by the time you got it to accept the "right" number, you could be dead. Three people in the vehicle called out the number to the sytem a minimum of 5 times each before one of us finally got it to dial. I'm not sure how the other part (emergency locator and response) would have worked as it was never tried. Maybe it works ok in some areas and not others, like cell phones, I don't know - I'm not "that" familiar with it, but that was my experience, limited as it was. I know others seem to have good reports.

Code - has had it's place in history - be it with the Titanic however it helped - to maybe others stranded. We don't know about any (or many) "military" use(s) where it may have helped out, we don't always hear about those things. Is CODE the "saviour" of the world? NO. Each mode or language if you choose to call it that - has it's own heroic moment at some point. Even Smoke Signals (if truly used/existed) probably had SOME helpful value. In a sense, smoke signals STILL exist. They use them at the Vatican to signify certain events - more notibly the death of a Pope. Simply put - you use what you have available at the moment - be it smoke signals, sun light off a mirror, code, fax, voice, drums, whatever. Anything is better than nothing in time of need. Seriously, I don't understand the argument over

Code. Times change, things change. We could argue the use of the smoke at the Vatican when a PA system would do the same job.

With each advance in technology, something goes off the shelf and tossed aside or if kept on the shelf, gets serious dust collections due to little if any use. Electricity replaced candles and lanterns for the most part - though not completely. The Telephone didn't automatically discontinue all other forms of communication - ie, code. The fax and e-mail have not yet altogether replaced "mail" but some day it may. We as a whole can choose to keep something by "using" it or losing it by NOT using it. Things just don't disappear overnight. IF ya like code - USE IT. IF ya don't, then don't worry about it. "IF" you need it to get a license - 5 wpm is not that hard. You won't get it by osmosis. It takes some determination. Just like studying the book. Nothing in life is worth much if just handed to you. There are myriads of things we "must" learn in life which may never be used again - it goes with the territory of life and getting through it. I had to take a course in college once to jump through their hoops. Have I ever used it since? HELL NO. No plan to - either.

As to the Titanic operator being a smart ass as someone alluded to in here - maybe he was just losing his cool (very afraid) and trying desperately to get help and felt any other signals were just going to interfere. I don't know - just my own supposition. People do strange things in an emergency and staring death in the eye IS an emergency. Maybe he screwed up, maybe things could have went differently - we'll never know. FATE has a strange way of playing out in all our lives. We can argue all night long over the "would haves and could haves". Nothing will change that course of history. The fact remains, he at least got the word out and SOME people were saved. ALL could have been lost - were he killed prior to the sending of the message AND if no one else aboard knew how to operate the equipment. He was just a "player" in the scheme of things. Had they not hit the iceberg by whatever faulty(?) piloting or directions being given in the first place, the Radio Operator wouldn't even be the issue. We had an incident here when I was but a teen. A "firefighter" had a problem - losing his cool, he got on the radio and said "Clear the airwaves, we have a national emergency". Yes, they had a problem, not of "national" proportion, but he lost his cool and went overboard in what he did with the radio. People - even stone hard natured people - panic given the right scenario. FRIGHT exists in all of us - at some time. Panic is the response.

GPS, CODE, ONSTAR - NOTHING (except perhaps radar or sonar) would have told them the icebergs were there. Even if they knew they were in a section of water where there were "known" icebergs that they could have steered away from, - as we know - icebergs can and DO break off - so this one "could" have been such a case. It was a doomed mission just as any that the Astronauts have been killed on - even with all the so-called advanced technology and communications at their disposal. Any number of people could be pointed to or "what ifs" asked. The point is, the end is still the same. People died. In the latter case, NO amount of radio comms modes would have made a difference. Just like the spotting of the iceberg at the last minute - so too was the spotting of the problem in the heat shield and

equipment - aboard the shuttle - too little - too late - with or without radio - regardless the mode.

Just my 2 cents.

Lou/Ka3flu

It was before the Titanic hit the iceberg that the Titanic
CW operator told the Californian CW operator to get off the
air. He considered his normal Titanic CW message traffic to
have priority over any CW traffic that the Californian might
need to pass. Turns out the Californian's CW operator was
the only person in the world who could have saved the life
of the Titanic's CW operator.

Cecil I will conseede the CW usage could have saved lives could still
save lives

but that was never the question

the question of the thread is could you save a life with CW is the
chance came
I am sure you could.

I could I certainly I could by very different means

could I save lifes on HF if the need arouse certainly I could do so
except I do not listen them nowsince Ican't use them as rotuiene matter

which would save more life and property maintining CW testing to keep
many of the current tech from aquiring HF experence or droing the test
al though us sue of the bands and the abilty to learn in an evionment
that assures there is some one out there to talk to someone

The first thing to go out in a disaster is the phone system. The cell
phone system is not immune to this problem.

A long time ago a guy I worked with told me that when he was in the Army
he was assigned to the artillery. He could not qualify as a forward
observer because he could only work 20 wpm and needed to be able to do
30 to qualify as a FO communicator.

Is CODE the "saviour" of the world? NO. Each mode or language

The radio operation on the RMS Titanic was controlled by the Marconie
Radio Company. As such the Titanic radio operator was discouraged from
communicating with any station controlled by another company. This is
called free enterprise. Also the radio was not under the command of
Capt. Smith. This was changed after the sinking. They also mandated 24/7

monitoring of the emergency radio frequencies.

>FATE has a strange way of

The Canadian Coast Guard and the United States Coast Guard expend a lot
of time and money looking for and tracking these icebergs. After the
Titanic went down the International Iceberg Patrol was created. It even
functioned during the Second World War giving positions report to allied
mariners.

It was a doomed mission just as any that the

Ship born radio communications were controlled by communications companies completely separate from the ship. The radio operators were not under the command of the ship's captain. In the case of Titanic the Marconi Radio Company controlled the radio. Californian and Carpathia had different company control and there was a definite rivalry between the companies. The Titanic operator was fully justified in telling the Californian operator to close station. This was one of the direct causes of the formation of the international radio treaties we operate under now.

> In that case then - I stand corrected, I was unaware of that.

It's totaly untrue. The Californian's radio operator ignored the
Titanic's distress signals because the Titanic was a Marconi ship and
the Californian was a Telefunken ship. The operators were not allowed to
communicate with the competing company's operators under any
circumstances under penalty of being put off the ship at first landing,
with no hope of getting home or being hired by the other company.

I recently blogged about it:

http://geoffstechno.livejournal.com/2006/06/22/

Geoff.

If the History Channel got it right, the Californian's CW
operator was asleep by the time the Titanic hit the iceberg.

I have a funny problem here. I am using my dual band radio, a Kenwood TM-G707 as a simple scanner and I have a problem in isolating a signal. If I open the squelch manually most of the way, I receive a signal from 400 to 523 mhz everywhere. This signal is on 24 hours a day but seems to be modulated only part of the time. When it is modulated, in FM mode, I hear a tv station crew doing their stuff to mount a program. I can hear the producer giving orders to the cameramen and also the script girl. The mikes are on all the time and not switched. I can't identify what station it is but this has been going on for many years. what I would like to do is identify the exact frequency they use but they splatter all over the band. Is there a way to really zero on them? Since I live in the Montreal area, it could come from everywhere but Iknow it's not coming from my town because no one does that kind of free lance work around here. I am really baffled and would appreciate some sugestions. Thanks.
Mike.

Chas,

Pienso que su problema de ruido en 75m y 40m es de fuentes locales.

Si no puede encontrar el ruido en su casa o las casas de sus vecinos,
es posible que un MFJ-1025 o un MFJ-1026 cancelador de ruido puede
ayudar, especialmente puesto que usted tendrá antenas múltiples. Son
absolutamente baratos para el funcionamiento.

También, una antena de lazo pequeña pudo ayudar. Tiene muy
profundamente anula y es muy es muy eficaz contra ruido local. Las
anulas son hasta 60dB si está construido correctamente.

No pienso que NVIS curará el ruido, pero hará cerca en señales más
fuerte concerniente a él.

Siempre bueno poner su política en la firma... gracias al senado!

Hi Mike

An intermod product? Fundamental overload? Modern broadband design amateur radios arent renown for good selectivity in strong signal environments... I doubt they "splatter all over the band", its most likely your receiver possibly in tandem with some other strong signal mixing in the front end. It may even be coming direct to the IF.

First suggestion is to use a smaller antenna (thinking its an overload situation). A directive antenna would be next with an inline attenuator and scan around. Keep in mind that the signal you want to hear may not even be in the radio's normal band coverage. Next is to try a different radio (design) and scan with that. It is probably also worthwhile listening to determine who they might be, then do a online database lookup (if Canada has it) for that organisations name!

Cheers Bob VK2YQA

Hi Chas,

Bobï¿½ asked for other tests that you either haven't done, or haven't reported.

You need to examine more than antennas to solve your problem. I had a noisy TR relay that did the same thing (bad contacts).

A good tech will attempt to partition his station by halves to discover the source of noise. For you, simply short the input of your rig. Does the noise go away? If so, your problem is external to the rig (there's every chance that your problem is here, there's every chance it isn't). A simple test like this can eliminate a world of grief.

Bobï¿½ suggested killing power around the house. A very good suggestion that removes local sources from remote sources. It is also a very simple one too. Running off a battery with the complete house shut down can tell you what your noise floor is.

Time of year is significant, along with weather conditions. Is this noise seasonal? I had a bad telephone ground that got worse WITHOUT rain (I live in rain city, so this was only an occasional problem that seemed insoluble).

Your report:
>there is no real static or tones or motorboating or anything distinctive. It
>is just plain, old NOISE!!
is quite odd in that static is classic plain old NOISE!!!!!
You need to be more descriptive because this is not plain at all if it is distinctly different from static.

If you have a portable SWL radio (or just an AM transistor radio), you need to walk the neighborhood and see if the noise is generally heard, or just on your block, or just in your lot. Neighbors with fishtanks are a leading culprit.

<< Troll message clipped >>>

I'll byte...

Someone can correct me if the order of my time-line is off...
Here goes what I can piece together.

Before radio, people used homing pigeons and wired communications.
This was the means of comms during WWI. If the wires failed or were
cut, the troops would send important messages out by carrier or homing
pigeons. As technology developed, the Radio was invented which
allowed CW only communications via Spark Gap. There was no voice so
ALL operators learned Morse Code.

Later, AM was invented and the voice could be heard across the radio.
This newer technology wasn't as reliable as CW, but became more
popular and more reliable as time progressed. Eventually, SSB was
invented. However, CW was maintained as the communication standard
for distress signals from ships, for two reasons. One: It could be
heard and understood even when someone wasn't tuned precisely on
frequency. Two: An invention made for ships created an automated
transmission of SOS and the ship's location coordinates. This could
not only be heard when tuned off-frequency, but also across a very
wide band of frequency.

Eventually, Satellite technology became a new standard. Now, instead
of having to calculate a ship's approximate position using LORAN
signals, a ship can know within 100 feet where it actually is. Also,
with that technology, comes a new generation of two-way
communications. Now, during a distress, the ship not only
automatically sends an SOS and it's coordinates within just a few
feet, but it is sent to monitoring rescue services who can find the
ship much more quickly than before. Now, regardless of the sun-spot
cycle, the time of day, the meteor activity, and band conditions, the
ship in distress can take only a fraction of a second to send an
emergency message in plain english (or native language) and receive a
notice that their message has been received and is being acted on just
as quickly. Not only that, but ANYONE on the ship can read and
understand the message. They don't need to have a specially trained
CW operator to interpret it and write it down for them.

Sorry, I love to operate CW, but if it is that important to emergency
comms, maybe we need to convince OnStar to convert to CW to be more
effective. I don't think they will buy it.

I don't think the question should be "If you had to use CW to save someone's life...?", but rather "If you had to save a life, what reliable technology do you have ready and available to use?"

Depending on the member of my club, the answer could be any of the following: CW on any ham band, SSB on any ham band, FM on any allowed band, Packet radio, Satellite communication via FM or SSB, Thru the ISS, Digital voice, APRS, Cell phone, CB channel 9 or 19, (yes, it can be very handy in an emergency), OnStar and similar services, and probably some other mode which does not come to mind at the moment.

Having worked communications in the aftermath of several disasters, I have come to believe that there is no less reliable method of communications than HF SSB. However, I have never seen conditions so bad it couldn't be used quite effectively.

Several years ago I conducted an experiment three times during a day: in the morning about sunrise, at lunch time, and in the evening about 6pm. I laid a 20 meter dipole on the ground and, without an antenna tuner, I transmitted an emergency drill cq on 20, 40 and 80 meters in SSB mode. In each exercise I found someone who could copy me clearly within 2-4 states of me on 80 and 40 meters. Even during the prime-time net period on 75, I got responses indicating adequate conditions to communicate the emergency messages. I was informed by one ham I drew him out of the woodwork as he has been listening but not transmitting for the last four or five months. The rig I used, an Atlas 180 drops power at high swr to 5-10 watts. The antenna was a 20 meter dipole with no balun attached directly to 75 feet of whatever coax the cable company uses to bring CATV into the home with.

20 meters only worked during the morning and at lunch time.

People are listening and the word "emergency" will get attention! Even appliance operators can answer that call. Could they answer you if you sent a distress in CW?

>... Thank Thor Friday Nears!

I don't think it would work. The reason is that the bearings that
must turn will likely only be located on the bottom section expecting
the antenna weight feeding down in that direction. Twisting left and
right is a different problem from hanging upside down. The top of the
rotor may not have the kind of thrust support for any bearing that may
be there.

I can't say for sure whether or not it will work without actually looking at the specific rotor's construction, but I can easily imagine that the engineers would not have included an upside down option as it would add significant cost to hundreds of thousands of rotors only to be used by a dozen or so....

Rather than speculate, I would suggest contacting the manufacture of the specific rotor in mind.

560. Some infos about Antennas in the world web site.

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-14 07:22:37 UTC
From: oli <oli004@wanadoo.fr>
Message-ID: <44b74643$0$830$ba4acef3@news.orange.fr>
Source record: 56297

Good morning gentlemen,

Some days ago, I have put online a website to show
antennas for all band and from everywhere in the world:
http://www.antenna-street.com/antennas

We are hundreds to practice radio on differents band and to have web site
to show our working conditions, qsl, locations and... Antennas.

Well, If you have a web page on your site who show your antenna(s)
I would like that you submit it in "Antennas in the world"

How does the site works :

It is like a database, But the only informations published are :
a picture of your antenna, the link to your website and a short
description of your antenna. That is all !
Ex : http://www.antenna-street.com/antennas/yagi-stacked-p1-15.html

When you submite your link, you give some few informations like :
1) Name or qrz : It is only internal information
2) Email : also internal info uses to confirm that your submited link
has been validated. You will not receive spam ! and your email is
not transmited to anybody !
3) Country : Information about the country where the antenna is
4) Locator : Optionnal information, you can give your city or your
locator if you know it, or just let a "*" (also for country)
5) Title : You can write the model
6) Site url : The link to your webpage or picture
7) Url image : This optional picture, if you don't give a picture url
you will see a white picture and a view of your web page some days
after.
8) Description : To give informations about your antenna if you want

Well, thank you to read me, and I hope that you will insert your antenna
page or picture in "Antennas in the world"
http://www.antenna-street.com/antennas/

Best regards
Oli

>> have priority over any CW traffic that the Californian might
>> need to pass. Turns out the Californian's CW operator was
>> the only person in the world who could have saved the life
>> of the Titanic's CW operator.
>

Firstly the Californian's r/o was not told to get off the air, he was told to "Keep out, I'm working Cape Race" while the Titanic was sending Passenger telegram messages to Cape Race shore station. The Titanic's r/o was just fed up with stations butting in, the "Break-Break" syndrome. The r/o on the Californian was in-experienced and failed to prefix his message correctly, this brought about the rebuke from the Titanic who thought he was just chatting.

It is also thought that it was the same failure of the MV Mesaba's r/o to correctly prefix the last ice warning message that was received by the Titanic that meant this message was not sent straight to the bridge, rather than being left with the other routine messages.

There is no evidence that the Californian heard any radio distress traffic until the r/o came on watch the next morning. They did however see rockets from the Titanic.

> if you sent a distress in CW?

In 1995 the ARRL commissioned a survey of ham radio operators licensed in the U.S. by having passed a morse code test. (5wpm on up). 64% of the hams responded that they NEVER used morse code. The ARRL published the results as 36% responded that they used morse code at least occasionaly, but the truth remains that over 10 years ago, you had a one in three chance of the person hearing you being able to copy your message.

That's why there was an international agreed to distress call, although at the time, radio operators were NOT obligated to listen or act upon it. "CQD" was not a distress call per se, it was Marconi company code for "assistance" as in "CQD CQD CQD" meaning send assistance and "CQD?" meaning "do you need assistance".

Telefunken operators were not privy to Marconi company internal codes, and were forbidden by company policy (and Marconi's) to answer them. Of course nothing is secret for long and it is quite likely that most Telefunken operators heard the CQD call from the Titanic, understood it and listened, although none of them were going to do anything about it.

When the Titanic operator sent the new distress call (which I can't write due to text limitations) of ...---... as one continuous string (not the letter S followed by the letter O followed by the letter S), anyone listening knew what they were sending. The confusion to the reader of this is because it is written as SOS with a line on top of all three, so if I could do it,
---
it would look like: SOS but here it looks like I am underlining with.

However the Telefunken radio operator on the Californian may or may not of heard it, but he was forbidden by company policy to reply or tell anyone about it.

The Cape Race story and his having gone to sleep was a cover-up.

For sake of brevity, I'm not going to repeat the entire story and references here, but you can find them in my blog entry I pointed to in a previous post.

So while sending SOS or any other morse code signal would be a good idea if you have a CW only radio, calling "MAYDAY" in voice would be much more likely to be answered.

It also depends upon where you are. Here in Israel, calling anything on CB channel 9 will probably not be heard, calling MAYDAY on 2 meters, will get you a "roger beep" from the repeater and nothing else. You'd better have a cell phone and know how to call for help. 911 (U.S.) and 999 (U.K,) are not used here, 112 should work on GSM phones, but the real numbers are 101, 102 and 103.

Geoff.

If you look at the radio logs you will find that Titanic only used SOS once
at 12:45am, and that was to MKC - her sister ship, the Olympic. The callsign
MKC indicating that she was also a 'Marconi' ship. The rest of the time CQD
was used.

Also to explode your theory even more at 12:15am Frankfurt DFT replied to
Titanic's CQD;
12:26 DKF (Prinz Friedrich Wilhelm) called the Titanic;
1am DDC (Cincinatti) replied to Titanic's CQD.
etc.etc

None of these were Marconi ships!!

and finally the Californian (MWL) was also a Marconi ship!!! So no
Telefunken operator to ignore any CQD's.

Regards
Jeff

I forgot to add that that is also not correct.

For British Ships at least, and I expect most other countries had similar legislation, the Merchant Shipping Act, did and still does *require* a vessel to render assistance to another vessel in distress; regardless of how you find out about it.

You are confusing it with the fact there was no requirement to keep a listening watch for distress traffic.

Do you have any documentation of that? I carefully searched and only found references to the Californian being a Telefunken ship. I have NOT found any contemporary listings of ships, which company operated their radio rooms, their callsigns, etc.

I would welcome them.

Thanks,

Geoff.

You have to understand that in 1912 radio callsigns were not internationally allocated, an M prefix was used and allocated exclusively by the Marconi company, it did not signify that the ship was UK registered..

Of the twenty six ships in the area and involved in the incident, twenty were Marconi ships, Of the rest one was a USA warship (USS Chester), four were German (with 'D' callsigns}) and one was Greek (with an 'S' callsign).

The 'Marconi' ships were:
ANTILLIAN MJL
ASIA MKL
BALTIC MBC
CALIFORNIAN MWL
CARONIA MSF
CARPATHIA MPA
CELTIC MLC
CEDRIC MDC
FRANCONIA MEA
EMPRESS OF BRITAIN MPB
LA TOURAINE MLT
MOUNT TEMPLE MLQ
MESABA MMU
MINNEHAHA MMA
MINNEWASKA MMW
NOORDAM MRA
OLYMPIC MKC, later GLSQ when national callsigns were introduced
PARISIAN MZN
and of course TITANIC MGY (was originally MUC)

Regards
Jeff

SOS ?

http://jproc.ca/radiostor/titanic.html

http://www.marconi.com/Home/about_us/Our%20History/Marconi%20Heritage/Titanic%2090th%20Anniversary/those%20saved

"The closest, a mere ten miles (16km) distant, was the 4,000-ton
Californian. Cyril Evans, its solo Marconi operator, like those
on other ships, had been warning of icebergs since the previous
afternoon and at 19:30 had drawn attention to three 'large' ones
in the immediate vicinity. At 23.00 hrs (ship's time) he tried to
send a further message to Titanic warning that the Californian was
stopped, surrounded by ice. He was told by Titanic to "keep out" as
it was in communication with the Cape Race station at the time in
connection with passengers' messages. Evans then retired to bed."

Well at least your estate will get to keep your life savings. If you get
sick late in the year, and the healthcare facility/hospital shut down
for the rest of the year because it ran out of government money (a
typical scenario in Canada), there will be no one to give you any care
and you'll just die. But hey, your life savings will still be intact!
Is socialized health care great or what?

Hi, Mike -

I've heard a similar signal just above the 70 cm band (above 450 MHz) but I don't remember the exact frequency. It was a local AM radio station using that frequency for remote broadcasts like, say, a little league baseball game. While not actually rebroadcasting the game, I could hear all sorts of stuff going on. They even occasionally used the frequency as one half of a duplex communications link as an aid in getting everything set up. The other half of the duplex link was the AM radio station!

Sounds like you might have something similar in your area, but perhaps the signal is so strong that your receiver is overloading so as to make the signal appear wide. Or, maybe they're also broadcasting the video as well. As you know, video is very wide (but not 123 MHz wide).

You could try a different location to monitor them and see if the signal narrows down some. Otherwise, try to zero in on the voice frequency.

Just a guess.

Cheers,
John

I agree, I've not actually seen any of the research about the platforms themselves, but as well as the airships there are also some unmanned solar powered wing planes have been tested too I think.

I'm sceptical myself, but it will be very interesting to see if it ever takes off! (no pun intended ;-))

Well, I for one am not going to instantly take the view that my lecturers' credentials are not solid. Of course they're going to put positive spin on it, mainly because for their part (physical layer and comms protocol stuff) they've been successful so far. Trials in Sweden were a total success, albeit on a smaller scale.

I'm still not convinced that the idea will ever actually be realised, but nevertheless it's still a very interesting one!

> You've missed the point Roy made. Adding connections (more HAPs) does
> not add more bandwidth. Those extra HAPs will be competing for the
> same (now diminishing by proportion) spectrum.

That'd be why there is ongoing research into the various multiplexing techniques so many users can use the same piece of spectrum and not cause *too much* interference with each other. Using spreading codes etc the other signals just appear as a little bit of extra background noise so I am led to believe. (I will get the full story on this sort of stuff in the next academic year).

Surely though even for broadband internet home users will not need to exceed 10Mbps speeds, what would be the point? Who needs to get a web page served a second faster, bearing in mind bandwidth limits at the server end as well as the end user connection. The 3rd generation mobiles were not looking to exceed 5Mbps per handset (which is a hell of a lot of data) at the very most and that is more than capable of streaming video etc (albeit at lower resolutions for the handsets).

The bandwidth requirements for cellular voice calls is minimal in comparison to data requirements. A phone line is only 64kbps, and cellular (gsm) data rates are less than that even and still provide good (enough) voice reproduction!

> When there's existing hardware (after all, no one is telling the
> consumers to throw away their phones and buy HAP versions), and
> Hindenberg technology is a century old; then any proviso "there is
> still a lot of work to be done" translates into SEND MORE MONEY - a
> message tape with an infinite loop.

Basically as I understand it they'd be looking to use current Wi-Fi, Wi-Max and GSM technologies etc so why would there be a requirement to

change hardware?

The only thing that would need changing with the broadband data downlinks to serve internet would be gateways with directional antennae to serve buildings etc.

This is the same with any new technology! Just look at 3G services in the UK, it's taken them a while to get network coverage any where near comparable to the already existing 2 and 2.5G network infrastructure.

Do you suggest that we just give up carrying out research into this sort of thing? Maybe we should have stuck with the original optical telegraph rather than develop methods of signalling using electricity...

I have no personal/pecuniary connections with this project, as I'm only an undergrad student, but I think to dismiss it out of hand as a non starter is a bit harsh. It does have the potential to work, whether it ever gets deployed is another matter...

I think that the facts are that this whole episode was right in the time line of the transition from the more or less official original distress signal which was the 'CQD' cited here and in many other references, to the 'SOS'. And .. had the operator of the Titanic actually been using the then newly 'adopted' 'SOS' distress signal, it is actually likely that the Californian marine operator, even though he retired and went to bed *MIGHT* have caught the call for help in time and many more lives had been saved.

As I think is the correct history here, the real reason for the as-thought need for a better distress signal than 'CQD' was precisely over this exact type circumstance! The Morse Code difference in the pure sound pattern between the very common 'CQ' (Call Quarters) and 'CQD' (Call Quarters Distress) is really a rather complex sound pattern. Which if one is awake and paying attention to the sound of the calling frequency channel, is different enough to attract attention.

However that is *NOT* the case, if .. while 'in quarters' ... one is asleep but still in an environment when the emergency 500Khz calling channel is there still coming over the speaker in the shack. As I've

been taught, this issue is one that adding that 'dah dit dit' to the 'CQ' is really, an issue when one is asleep and has it jangling in one's asleep ears, of a garbled sound pattern. It is just like the over and over again 'CQ" that one heard at the time and thus, in one's sleep, would tend to be 'not significant' as a OH WAKE ME UP distress call! You go right on snoring!

Contrary to a lot of opinions that 'SOS' means "Save Our Souls" or "Save Our Ship", the 'SOS' Morse Code pattern was chosen for one specific reason. It is the absolutely clear unique sound pattern of the "Dit Dit Dit Dah Dah Dah Dit Dit Dit" pure sound pattern which .. even if an operator were asleep in the shack and the 500Khz calling channel distress frequency were playing .. could actually be unique enough as to a sound pattern to awaken the sleeping operator. And if it did, that would add to the possibility of saving lives and handling whatever was wrong for the poor ship in distress.

Thus .. purely conjecture at this point .. had the operator of the Titanic actually used the newer 'SOS' distress call and the operator of the California been awakened by it, perhaps many more souls could have been saved in the sinking of the Titanic.

One of the most interesting books which has all this in it is:

"SOS To The Rescue" by Karl Baarslag
Copyright (c) 1935 by Oxford University Press, New York, Inc.
Special Edition published by arrangement by Cadmus Books
E. M. Hale and Company of Chicago

A treasured copy of this book which is in my possession is one of the real motivational forces which moved me steadily forward in CW toward my original WN5WQN Novice call here in the USA in 1952. And as soon as I could take it, to one of the early Extra Class tickets thereafter. At that time .. so told me .. I was the youngest person in the USA to have been issued an Extra Class, by the examiner in Buffalo, New York, where my Dad took me while the family was on summer vacation in Erie, Pennsylvania as a kid.

Do not think for a minute that if you are in still yet a few professional work disciplines, that sending 'SOS' cannot save lives. It can. And yes, I have proof i person of how that can still be! As a high time FAA Multi-Engine Instrument Flight Instructor in a part of my past life, there is actually a formal life save citation in the personal record of a long ago FAA employee at Easterwood Airport who worked in the FAA Flight Service Station there, now long deceased. His name was Ted Wiley.

During a serious IFR flight in a single engine Cessna 172 N1784F way back in the 1960's from Dallas, Texas to College Station Easterwood field, no radar in the little plane and all that .. the silly microphone failed! No transponder at that time in the little Cessna either. So no distress signal possible with that method. In the middle of all the TRW activity and so on I had an idea. I ripped the wires out of the microphone and pinched the keying relay lead under the metal clipboard hold down of my pilot's kneepad note board. Then with the ground lead, I began sending 'SOS' in Morse Code to Fort Worth Center .. and

the airplane tail number.

Back came Fort Worth Center, "Aircraft on CW, do you read me? If so send Morse Code dots only." I sent back an single dots several times. Next came, "Aircraft on CW, stand by while we find someone who can copy CW please!" I waited. Then came the following from Fort Worth Center, "Aircraft on CW, send your call sign." I sent it. Came back, "Aircraft on CW are you N1784F?". I sent several "R"'s.

From that point on, the whole flight was carried, TRW diversions and all, with the FAA circuits patched to the FAA person who was doing this, all the way from about half way between Dallas, Texas (DAL) and Waco, Texas (ACT), thence all the way to College Station, Texas (CLL) totally on CW on my end! That included even the whole instrument approach clearance, landing clearance; eveything.

And .. in fact .. when we broke out of the clouds just above minimums on the VOR 12 approach at Easterwood Field, the FAA person doing the 'save' asked, "N1784F, Easterwood Tower wants to know if you'll send them a ditty dum dum ditty?"

Just before the wheels touched the runway I did that! And at that moment I looked off to my left over in front of the main hanger where the offices of Texas Airmotive Company were, for whom I was the Chief Pilot for the Texas A&M University contract ROTC Flight Training program at that time, as well as where the FAA Flight Service Station was. Out in front was a whole line of people who were cheering that save!

And that save is formally in Ted Wiley's record and was published in the USA FAA official employee paper as a life save for him. Who did just exactly what this topic thread questioned could be done. If somebody ever called SOS and ever needed help on CW, could a life be saved? Answer; yes!

It also can still be done today, though not very many commercial pilots think so. If you call 'SOS' on CW 121.5 Mhz or whatever channel you are in communication with the FAA upon, they *CAN* drag up someone who can copy CW. Even if they have to patch the audio for the communications channel to afar to do it. And they *CAN* act on even CW communications to do whatever can be done to even save lives this way. If need be. And they will. So this is one place where that is still true, grin.

W5WQN

At that time - Commercial Pilot ASMEL & Flight Intructor 15128600
And at that time - Commercial First Telegraph License # T1-HQ 3645

Which curiously, are still two licenses which, although not really well known, can get you a letter from the President of the USA calling you to service at any time for the rest of your life in time of crisis. But at my age and of the every-day importance of CW, I rather doubt such a letter would arrive at this point in my life, carried by the two officers who normally deliver it. And yes, I do know of two men who have in past years gotten such a letter! Although both were in the Instrument Multi-Engine Flight Instructor group of people.

How about mounting it rightside up but putting the mount in the top and
antenna on the bottom ?

I got some 1 1/2" plastic pipe threaded on one end and threaded it into a flange that had 4 mounting holes, the piece of pipe was about 12" long, and screwed it to the floor in my attic and mounted a "RADIO SHACK" rotator and a small mast to the top and mounted a 2 ele 2m quad. Quad and rotator works great!

best 73's - de Howard W3CQH

The same problem. The thrust bearing is setup to support the upper
section of the rotor pressing on the bearing pressing on the lower
section of the rotor. (long complex sentence).

on the heady topic of "Attic antenna: rotator
upside-down work?"

My oppinion would be: that while it May, or May
Not work (depending on the bearings in it), The
MAIN consideration, tho, as I see it would be
WATER in the Control Cable connections, when a
Rotor is upside down (obviously NOT a factor ,when
mounted under a cover, roof, ect)! Probably will
work fine!
just DONT try this if EXPOSED to the Weather! Jim

In areas that aren't flat, reflection(s) on VHF/UHF from nearby hill(s)
and/or building(s), a map that shows the direct path for a signal may be
useless. Point the antenna where the signal is strongest or least affected
by multipath... no map needed. I learned that lesson when
installing/maintaining FM broadcast (67KHz SCA) background music receivers,
back when I was young and impressionable. Now, I'm not so young... ;-)

Still, the map would look good on the wall in the shack!

SOS had been the official distress call for about 3 years when the Titanic went down, but CQD was the long established distress call used by the Marconi Company. Marconi had such a strangle hold on marine radio at that time that old habits died hard. That said everyone knew what CQD meant regardless of the company they worked for.

I doubt that the Californian's R/O would have heard any SOS or CQD in his sleep. At that time it was general practice to shut down the Equipment when not on watch.The receivers needed constant attention to keep the coherers functioning properly..

Regards
Jeff

I got nothing against CW, but being kept out of amateur radio for 40+ years cus I had difficulty learning the code, sucks.
Finally, I got enough right to barely pass the 5 wpm test. Still can't find anybody slow enough for me to copy on the air.
If I ever get good enough to use it, I'll try a few homebrew transmitter projects.

I expect there are some technically competent people who might be interested in amateur radio, but have no interest in learning code.
John

Mike

I am an ex-broadcast TV worker. To me it sounds like a studio talkback
system that is left on all the time - not uncommon in regularly used
control rooms - but only has modulation when in use. From what you
describe of your neighbourhood it is unlikely to be front end overload
on your Kenwood.

To help track down the source it may be possible to figure out what
sort of programming is being produced by listening to the talkback; if
the same stuff happens at the same times of the week/day it is
obviously a regular show of some kind.
It is most likely to be a prerecorded show; the only live broadcasts
are news programmes and sporting events and the timing will give a big
clue.
"Run tape. OK, we got three minutes, reset for the singing sheep".

If it is a regular show, the direction will be fairly laconic because
the crew will be doing the same stuff over and over again - but you
might get the presenters' first names:
"Two, tight closeup on Tom. Three, loose two on Dick and Harry".

If it is a game show, anything up to six progarmmes might be recorded
in a day:
"Next is programme three. Autocue, can we change line four to 'our new
defending champion from last week is John Doe' "

Either way, your next step should be to Google TV production companies in the Montreal area, starting close and working outward. I suspect there will not be many with a regularly used studio. It is a small community so a very few calls may well help you zero in on the source.

In each case ask for the technical director and explain what you are receiving; in my experience he would be very concerned about the emission and take steps to suppress it as quickly as possible for a variety of reasons:
"OK three, gimme a two shot. One, frame a single on that visiting political asshole once makeup has made him vaguely human".

Good luck.

Pete

Not always. It's quite common to see a skip zone on even 75m.
It's more common in the winter than summer, but can happen any
time of the year. We are in the low end of the solar cycle, so it's
more
common right now. As one already asked, you need to determine if this
is normal atmospheric static, or some type of local line noise.
That you hear it on the higher bands kind of points to some local noise
being a problem. You say 1900? Is this GMT? Sounds like you are
talking in the afternoon...?? Or do you mean 7PM? ??
75m is unstable early in the evening. It's common to see a skip
zone where you don't hear stations close to you. Most of the time,
this clears up about 10-11 PM, but it varies... In the winter, in the
low solar
cycle, it's not unusual to see the MUF drop below 4 mhz between close
stations. But again, this will often raise back up later at night.
>
> A fellow on another site or forum suggested an NVIS as you have.

Absolutely.

> I am
> considering a 63' wire about 10 ft above and across the yard (which has about
> 4" of iron ore for a base) so I should get good reflectivity espec with all
> this rain. I might attach it to a 15x20' steel patio cover at one end if I
> can find a way to insulate the cover from the pipes into the ground. or do
> I want it grounded? I am getting so confused and frustrated. I can
> certainly remember in the 1950s how low the QRN was except for sunspots, etc.
> or someone with a "noisy" auto engine.

Forget the gimmick antennas. They won't help. How good is the antenna
of the net control station? Maybe half the problem is on his end?
Is he running any power? It's July. It's normal to have a high noise
level

at this time of year. S9 noise level is nothing unusual. So this means
you
need to use the most efficient antennas you can, and power won't hurt.
I have no trouble talking in the summer using 100w, but I run coax fed
antennas such as dipoles, etc. Right now I'm running a coax fed
turnstile
on 80m.
You mentioned what antenna you had, but I don't know what that is...
It sounds like one of those "all band compromise" antennas though.
I'd ditch it, and stick up a regular old coax fed dipole. Nothing you
can use
will be any better, or more efficient. Use a 1:1 balun, or a coax
choke at
the feedpoint to ensure you don't pipe shack noise back to your
receiver.
Forget the carolina windom. BTW, most any wire antenna at 35 ft is
going
to function as a NVIS antenna. Most of the radiation is straight up.
What
really counts is the total system efficiency. You don't want to waste
any
power in tuners, intentional resisters, etc... A coax fed dipole, loop,
turnstile,
etc is appx 95+ % efficient as far as the total system efficiency.
Some use full wave loops for NVIS on 75, but there is really little if
any to
gain over a 1/2 wave dipole. If parts of the horizontal loop are close
to the
ground, it's quite possible for the 1/2 wave dipole to outperform it,
if the
dipole is well up in the air. Max current is at the apex of a dipole
or
turnstile. So it's usually well up in the air away from ground. A low
hanging
loop can have high current points fairly close to ground. So I wouldn't
use a
horizontal loop unless all sides were fairly high in the air. Even
then, I doubt
if much advantage. I remember back in the 80's , I compared horizontal
loops,
and dipoles back and forth, and could hardly tell much difference at
all.
I came to the conclusion the extra work for the loop didn't pay off.
:/
I think the turnstile is slightly better than the loop, or the dipole
for 75m NVIS.
It's pretty much my favorite lower band NVIS antenna. The turnstile is
real
good on 40m in the daytime. Your memories of a quiet 75m were probably

in the winter...Wait about 4 months.. It'll get quiet again..
MK

though one would wish that clueless reports would refrain from scientific explanations:
<quote>
The actual electric charge in a flash of lightning comes from particles from the sun sent out in the solar wind which gather in the outer atmospheric layers before creating a strike.

</quote>

though at least he has also heard of the real explanation, though he even distorts that one and refers to it only as a theory, where the above is stated as a fact.
<quote>
Scientists are still divided by what actually causes lightning, with one theory suggesting falling droplets of ice and rain become electrically polarised(sic) as they fall through the natural electric field in the Earth's atmosphere.

Sorry John, do some reading for once as that is the reality of the
Canadian system. You'll actually learn something if you do research
yourself and not just listen to NPR and CNN.

Now, on the other hand, if you live in the U.K., you'll still have
healthcare through the end of the year, but if you are too old, they
just let you die as it is not worth the expenditure to keep someone old
alive even longer. But again, hey, your estate gets to keep the money!

Come on, this isn't really John now is it? Hillary Clinton, is that you?

John,

Just get on digital modes. Don't worry about CW. Digital is where the
fun is and the copy is much better.

A buddy of mine in St. Louis and I experimented with low power and
various digital modes last night on 40 meters. CW was marginal. The
best was DominoEX with FEC - just about 100% all the time and it also
has a second channel to display additional information.

CW can be fun at times, but maybe it's not your thing. Let the
stone-age hams continue with CW, and move up and on to the digital modes.

MultiPSK, while a bit cluttered and ugly, is a great program you can
use. MixW is cleaner looking and very good, but not as many
capabilities in the program.

Move on and start having fun.

What more can you expect from the London 'Daily Wail'?

(However, 'polarised' is perfectly good British English.)

If you want easy...and most of the CW whiners do...why don't you just hook your laptop up to your DSL line and stay the hell off the air?

Jeez, you've got a pathetic joke for an exam now with canned questions to memorize and no code to learn. Too bad you're not still in your mother's womb so you don't have to feed yourselves. Though you have deluded yourselves into believing you are "hams," you are hardly believable when you wear that title. The only reason you have been able to slip through into the dumbed-down requirements and some sort of fcc "license" sham is because your appliance manufacturers that make your rigs and the charlatans like the arrl are selling out the hobby so they can sell you things.

It's ALL ABOUT THE MONEY and you no-coder idiots have fallen for it.

As for traditional, genuine "hams, we may be from the "Stone Age," but once the dinosauers became extinct the pristine landscape took on pollution and overcrowding. You simpletons have all drank the Kool-Aid and cannot see that you are parties to the eventual elimination of ham radio.

Thank God for "stone age hams," for at least there is someone still around that knows something about the avocation.

>
> tnx

What do you consider a "Special Price"
Remember you BASIC economics -- and WATCH the Yen-Dollar exchange rates.
Hakko has attempted to keep their product prices the same --
as the Dollar has devalued against the Yen.

My advice: Last time I saw these factors (1973; 1979) with energy price increases -- inflation and price increases followed within a few months or the year. IF you want one - find best deal today - and buy it - and do not be surprised if the price rises 10% over next 18 months.

eBay has about the best prices for the Hakko 936-12
A majority of these sellers are large Hakko distributors or dealers (TE equipment, HCM) - selling excess inventory. IF you want best retail store price - checkout Fry's Electronics.

BEWARE of bargains or very low prices -- you may be buying a Chinese copy of the Hakko products.

Web sites can be found on Internet that show side by side pictorial comparisons ---inferior vacuum pumps (desoldering stations), poor assembly quality and ceramic iron heaters that are not of the same quality or construction --- as the true Hakko (Japanese made) heaters.

Hakko USA web site

Nothing said about any "error" in the definition of "(sic)".
The use was entirely appropriate for a largely US audience.

And your drivers' license test was what? Did they test you on
rebuilding your car?

>Too bad you're not still in your mother's
> womb so you don't have to feed yourselves. Though you have deluded
> yourselves into believing you are "hams," you are hardly believable when you

Well as a supporter of getting rid of the out-dated CW testing
requirement, I passed my test 35 years ago and a 13WPM CW exam. So I am
one of what you called a "genuine ham" but still have the intelligence
to know that a CW exam is old, stupid and mostly supported by a bunch of
stone-age hams who whine because they had to pass a more stringent test
and can't accept that others are not having to study for and pass a more
stringent test. Waaaaa, Waaaaa, Waaaaa.....I want my CW. Blah, Blah, Blah.

> wear that title. The only reason you have been able to slip through into the

> appliance manufacturers that make your rigs and the charlatans like the arrl
> are selling out the hobby so they can sell you things.

That is somewhat true. So what. Heck, what does a test even prove
anymore? I can have 440 handheld family band transceivers with the same
power as many small ham handhelds. I don't need a license to use those,
so what's the big deal about stringent testing requirements for hams.
Test hams only on the legal issues and rules. We don't really even need
the other crap anymore. It's not like we dealing with lethal voltages
all the time like the days of ol'.

>
> It's ALL ABOUT THE MONEY and you no-coder idiots have fallen for it.

So what if it is about the money. You need money to live on right?
What's the matter with spending money to create jobs from manufacturing,
selling, fixing, etc. ham radios. Maybe it's also about having
experienced radio communicators in an emergency and a lot of extra

equipment in home inventories.

>
> As for traditional, genuine "hams,

What is a genuine ham? Someone who knows CW? That's a laugh. Look at
all the bickering "genuine hams" who passed that all important test and
13 or 20WPM CW and who argue and fight on the bands. Did you listen to
75 Meters? And I mean going back 30+ years ago? Your testing did not
stop the idiot "genuine hams" back then now did it?

Cecil, rather than help people with questions and give them good helpful answers you seem to just want to turn it into a peeing contest. Even if you have to drop sentences to make it appear someone else is wrong.

Why do you do that??? Don't you think it is more important to help the guy asking the question than to play Cecil games??

Actually here is everything I said in CONTEXT. Tell me what is wrong in the entire CONTEXT of what I said.

> Would a sleeve stub work better than an open wire stub? It's certainly
> stupid to make the feedline MORE of an issue.

Look at what the J-pole really is.

1.) You have a half-wave end-fed antenna. There has to be as much common mode current leaving the end of that point and flowing down the feedline as there is flowing out onto the antenna at that point. There isn't any exception to this rule.

2.) While that current may be small with a perfect half wave, it is never zero. It gets worse fast of the antenna is not 1/2 wl long electrically, or if it is thick.

3.) Now you have a 1/4 wl stub feeding that half-wave on the end. If you perfectly floated that 1/4 wl stub, common mode current in the stub

would DECREASE as you move away from the feedpoint. But if you ground the 1/4 wl stub, current common mode INCREASES as you move away from the stub. This is why end-fed Zepps and J-poles model very good when a perfect ground independent current source is used to feed them. Unfortunately we can't do a perfect ground independent feedpoint in the

real world, so depending on the CM impedance the amount of pattern distortion will be all over the place.

This is why Zepps, antennas that are really just the same as a J-pole, are notorious for RF in the shack. The lack of feedlines in models are why people who do not include the feeder or feedline matching device to

the 1/4 wl closed stub conclude they aren't so bad.

Why would anyone go through all that bother to complicate the feed system in a Yagi is beyond me, when there are a half dozen easy solutions that were mentioned here.

73 Tom

<<end of quote>>

So you see, you mislead people on purpose Cecil. Shame on you.

You just don't get it do you. There are conditions for each mode that will make that mode "the best". Every mode has its place. That goes for voice, all the multiplicity of digital modes and yes CW. Last night you had the best luck with DominoEx. Another night RTTY might be better. Another night, voice might be more intelligible. Yet another night will favor CW.

Based on what I've read about DominoEX, it is a form of Multi-Frequency Shift Keying. This variation looks to be more robust than others, however, anything that can compromise FSK and MFSK has the potential to compromise DominoEX. It will merely be a matter of the degree of severity needed before it becomes unusable.

Just because something is old doesn't make it useless or stone age. Pencils have been around far longer and are still highly useful.

Actually it was a simple realization on my part that half the alphabet
was the mirror of the other. i.e. a/n f/l e/t etc. When I had this
epiphany I basically knew the code. All I had to do was learn to receive
it which I did successfully twice, once for my novice and once again
when I sat for my Tech before my novice license came. Passed both tests.
Haven't used it much since. My choice.

no you don't get it

CW is in radio terms stone age, simol e fact stone does not mean
useless you lack of ability to use english is worse than my problem
with it you can't use words even though you can spell em

A stone club is still leathal does that mean the army should drill and
train with stone weapons?
CW is obselete like HMS Canpous at the battle of the Falklands, like
the Bowmen that fought with em in the retreat to Dunkirk .

utility does not preclude obselenece

LEARN ENGLISH esp when yo u lhave played spelling NAZI your self

Thanks Dee, you admitted that CW is not the best mode in any condition.
You agree that different modes work better under differing conditions.
I agree. That's why is it utterly stupid to test incoming hams on one
mode of communication. Finally we agree on something.

Any mode can become unusable depending on conditions. The best thing is
that some digital modes can be decoded when you cannot even hear the
signal with a human ear. You just cannot do that with CW. With CW if
you cannot hear it, you cannot decode it.
>
> Just because something is old doesn't make it useless or stone age. Pencils
> have been around far longer and are still highly useful.

I agree. I never said do away with CW. I like to use it myself.
However, tube rigs suck more electricity than solid state rigs and are
bad for the environment so old things can be rather useless or damaging.
Just like CW, it's not useless, but continuing to have a CW testing
requirement is damaging and outdated.

Riding horses is fun still, but very few want them for the normal day to
day transportation now. They may be useful still, but for everyday
transportation they are no longer required. Horses are found more and
more out in the pasture where the CW testing requirement belongs.

Just found this thread. If I had to use CW to save someone's life, it would depend on a lot of variables.

Firstly, if it involved any of my own ham radio gear, it would be more than a little odd, since I have a mic for each transceiver and I don't own a key jack that would plug into any of them, although I do have a straight key, just no jack to plug it in with.

Assuming some weird contrived scenario where I had the equipment to send CW but not phone, it would depend what frequencies it worked on. If it was on the HF ham bands then no major problem, as there are still quite a few people who still use CW.

My own lack of real aptitude shouldn't be a real problem for two reasons. One, I could slow down to a comfortable speed, i.e. 5-10 wpm. Two, it would matter more whether others could copy my sending than vicea versa. I did pass 20 wpm, but have yet to buy a plug for my key, many years later. As I said though, that really wouldn't make a difference.

If you asked the same question to someone who had only passed 5 wpm and then, like me, never used it, then I suspect the victim wouldn't make it. But then in most countries there is NO morse code testing any more, so there are plenty of hams now who've never learnt atall. For decades there have been no code VHF hams in most countries anyway.

There again, if the key was anything other than a straight key, that would be curtains for the victim, as I would have no idea how to use it.

OTOH, if this scenario didn't involve the HF ham bands, then the victim would be as good as dead, as I'd never find a non-ham who could still read CW on the other end.

And your point was...?

Pot: Kettle, Kettle: Pot.

This was a deliberate dose of your own medicine. When you
stop the deliberate obfuscation of my postings, the problem
will cease to exist.

> Why do you do that??? Don't you think it is more important to help the
> guy asking the question than to play Cecil games??

You are the one who taught me to play those silly games, Tom.
Just as soon as you abandon your unethical methods of quoting,
I will stop mirroring your actions back at you. You have even
reverse-ordered the dates of my postings to make them appear
to mean the opposite of what they originally meant.

I know a few technical types who could be contributing to
this newsgroup but are afraid of attack from your junk yard dog
style. Your strategy seems to be to attack everyone who disagrees
with you and try to drive them off the newsgroup.

One of the QRZ moderators advised me to stop arguing with you
because "W8JI is never wrong, even when he is completely wrong".
He made me promise not to reveal his identity. Another individual
regularly sends me technical information to use against your
irrational arguments but makes me promise to keep his identity a
secret lest he suffer one of your attacks. You have intimidated
a lot of people with your attack dog style. One wonders why, if
you are such a guru, you need to adopt such a style. How about
a kindler, gentler W8JI in the future?

I'm willing to agree to a truce which limits your and my postings
to technical information and logical arguments. Are you willing to
give up your ad hominem attacks and obfuscation of my postings?

No that has nothing to do with whether it should be tested. We do NOT agree
on that issue.

CW is a valid and useful mode but it is different in nature from the other
modes. All the other digital modes simply require investing perhaps as much
as 30 minutes in setting up the hardware and software to get up and running
even if you make your own interface. So one can quickly evaluate whether or
not they will like it. On the other hand, it is impossible to determine
whether you will like CW until you have learned it, which takes some time.
Many people who might like it won't tackle it unless it's required as they
will have a false impression that it is too hard since there are so many
trying to get the code requirement dropped by trying to convince people it
is difficult. It is not difficult to learn but it does take time. I've
known a number of people who admitted that they wouldn't have tried it
unless required to do so but now find that they enjoy it. It's rather like
piano lessons. Every adult I know who took piano as a child has made one of
the two following statements: a) I'm glad my parents didn't let me quit,
or, b) I wish my parents had not let me quit. The very adults who, as a
child, were glad to drop piano are the ones who most deeply regret it now.

That is true but it is not a reason to condemn CW. It is merely a working parameter that one must deal with. Besides one can run CW at a higher output without risking damage to the radio to often make up the difference. Keep in mind that if you include the power requirements for the computer and monitor plus radio that a 25watt output signal for the digital mode draws more power than a radio putting out 100watts of CW.

I have repeatedly maintained that each mode has its advantages and disadvantages but the anti-CW crowd takes its particular characteristics as a reason to castigate it. They refuse to objectively evaluate their "high-tech" digital modes for their unique advantages and disadvantages. There are times when a voice signal will beat the digital modes in intelligibility. For example, PSK goes belly up with even the slightest auroral disturbance yet voices, while distorted, can still come through. It will take a higher level of auroral activity to knock out voice in comparison to that required to knock out PSK.

A well rounded ham should be able to select his/her mode on the basis of conditions and not be limited to by the fact that they were allowed to "slide" on the code training.

Who says you have to stick to tube rigs to run CW? I know you know better than that. Tube rigs have largely gone away (except for collectors) simply because its much easier to deal with solid state equipment. Yet if one wants to run a legal limit amp, it's going to be a tube unit as they haven't come up with a way to do it cost effectively any other way.

I strongly disagree that a CW testing requirement is damaging or outdated. There simply is not sufficient data to support that point of few. An occasional anecdote does not qualify as valid data.

> Riding horses is fun still, but very few want them for the normal day to

Again I disagree. That analogy is not really valid. A better one would be comparing it to driving an automobile with a stick shift. I personally feel that every one who drives should be required to know how to drive a stick. They often get better mileage than automatics as an experienced driver can do a better job of selecting the shift point than a mere gadget. More people might select stick shifts if only they knew how to drive one.

To "some" extent, I "may" have to disagree. I held a class once for "No Code Tech" and one of the guys - a man in his 70s asked if he could go for the code test even though I wasn't teaching code. He said he had learned it years ago in the service - but may be rusty. Let me tell you - when he was done testing, he had PERFECT copy. Was he practicing all along? We'll never know - nor did I ask. He has since passed on. Some people DO have a good memory and retain quite well. Others - lose things almost immediately if not used. Some of us, it takes a while to lose it and we usually do.

I am trying to make a powered shortwave antenna circuit for use with a shortwave crystal radio. I wanted the circuit to use power directly from the wall socket (AC 220V) so as to make a powerful and sensitive antenna out of a TV antenna or just a long wire.

Thank You,
Matthew William Coan

Not exactly your question but take a look at Circuit Specialists
CSI-STATION1A:

http://www.circuitspecialists.com/prod.itml/icOid/7307

This is basically a clone of the Hakko 936, uses the same tips and even
has the same schematic. I've had good luck with mine and the price is
right at $34.95 Someone on the QRP-L list thought that the Chinese
maufacturer might also be making the Hakko.

Caveat emptor & 73!

Sounds like you need an active antenna. Try Google on active antenna
and see what you get. An active antenna uses transistors or I.C's to
amplify very short or poor antennas to increase the signal strength.
Active antennas can be powered from AC mains with an appropriate power
supply.

With a crystal radio, normally you don't need any active devices. If
signal boost is desired, you can do it on the RF end (active antenna),
or on the Audio side (audio amp).
Good Luck.

From your written question - these observations.

1. English is not your native language. IF it is - your spelling and
grammar need work.

2. It appears to lack fundamental electrical and radio theory knowledge - a
good way to get electrocuted with commercial line voltages (120 or 220 VAC)
and appliances.

3. A crystal radio (shortwave) is limited by its overall sensitivity and the
RF from broadcast stations that it can capture by the antenna.
You just need a better antenna (higher in height or longer in length)

The Xtal Set Society
http://www.midnightscience.com/

Simple crystal radios
http://sci-toys.com/scitoys/scitoys/radio/radio.html

4. If you wish to improve the receiver - then you need to read Edwin Armstrong (regenerative and superhetrodyne designs)
http://world.std.com/~jlr/doom/armstrng.htm
who blazed this trail you are attempting almost 100 years ago.

5. I think you need to follow this line of construction for improving your crystal radio
http://www.techlib.com/electronics/crystal.html

http://www.thebest.net/wuggy/

http://www.schmarder.com/radios/crystal/

gb

"We who give advice or responses are survivors of the electrical and radio craft --

Dee, you can disagree all you want. The fact is that the world is moving on and away from CW testing. Not the mode, but the testing requirement. It is just outdated and not necessary. If you want to learn it and then use it, great. The time has come to stop forcing an old mode onto people. We can debate the merits of CW all day. In 200 years, no one will be using it. It will die a natural death like all languages because the world evolves. Better things come along. And like many humans, you are resisting change because people hate change. But change is inevitable. You cannot stop this change and it is a change for the better even if you won't admit it. History will show the only way to save the Amateur Radio Service and help its growth is to evolve and change. Out with the old and in with the new. Those that won't evolve will fade from the earth just like stone-age man. Good bye CW testing requirement. Your departure is long, long overdue.

Very well put. Every mode is useful, important and valuable in different situations. What's unfortunate, is that the only modes the anti-CW crowd wants and supports are "Lazy Mode" and "Retard mode"

Such an assumption...

I would like to remind the vaguely English speaking US audience that
there are more people outside the US that speaks English as their first or
second language - most of whom have a rather good idea of the world as
well.
Also, most of them actually knows that Switzerlands capital is, not
Stockholm...

Cheers

If you're going to point out how others use the language poorly, then learn to use the language correctly. The posessive form of Switzerland is "Switzerland's".

Stockholm is a very nice city; I especially like old town. It has some great live music bars. Too bad they tax alcohol so highly that the locals have to get smashed before they go out. 20 years ago a beer was 5 bucks, mixed drinks over 10, I shudder to think what it costs now.

Did you know that Sweden consumes over 10 times the sugar needed for cookies, coffee, tea, and other needs? I here it all goes into stills. Wonder if has anything to do with taxes?

Yes, just as long as it's still required to get a license and the speeds
need to be bumped back up to 13 & 20wpm again.

hi!

i wouldn't buy hakko, at least not for professional use.
i found it wasn't very good, the heat wouldn't transfer to the soldering tip
very well.
my friend changed all 50 hakkos to weller even if they are 3-4 times more
expensive !

cheers,
christine

Which Model Weller did he change them for?

I am looking for a new Iron thats ESD safe so i am curious. The
impressive thing about the Hakko is the extensive tip range. very few
irons have such a broad range, if they do they move you towards
professional SMT stations for SMT tips etc. With Hakko you can at least
get SMT tips for their cheap irons. Since i hand solder SMT this is
great for me.

Pray tell, oh wise one, from what source are you getting this information? You claim that this is a typical scenario in Canada, which is utter BS (= Bush shit), which means that it happens all the time. It seems rather strange that none of this seems to make the headlines or news.

BTW, I overheard this while I was visiting in Toronto and witnessed an accident: " Wow! The police and ambulance are much quicker here than in Atlanta".

That's not true.

You interact with others through obfuscation and bullying. I just wish you could control it a little bit becuase you do have useful things to say. Sometimes people want answers to questions Cecil. The J-pole is a good example where the focus should be on the antenna.

All of the models I've found on Cebik's site and nearly all of the models elsewhere lack a ground or mast connection at the shorted feed-stub junction, while most J-poles have that connection. They also use a floating ground independent current source, which virtually no J-poles have in the real world. I'd bet nearly all J-pole are eventually fed by unbalanced feedlines or feedlines with finite common mode.

The models, through pure accident or lack of basic understanding, use a BEST case feed simulation that masks all of the problems a J-pole has with common mode current.

No designer in his right mind would use such a lousy feed system to feed a pattern sensitive design like a Yagi antenna, they are barely acceptable as a omni-antenna.

I think I worked you...I have NEVER seen 6M this good (and I've been on 6M for 21 years now). Just about EVERY signal was S9 +60 (yes, +60!!!)...WOW!! Signals were SO strong, my Kenwood 690S receiver was being overloaded. The plus side was that I didn't have to rotate the beam...I worked people off every possible angle from the Yagi! Even work XE2 and VP9 and THAT'S not a daily occurence up here in EN45 (WI). It was open all day like that and was still open a little when I went to bed just after midnight. 2M opened up so I actually turned down 6 to go work 2M stuff!!

Maybe they just don't want you to know the truth? Not surprising, since the
government in CanaDuh woud fall if you ever discovered the truth.

Did the accident involve the police and the ambulance racing to the donut shop?
Maybe that's why they appeared to be quicker.

Sorry Blow Code, but you cannot turn back the hands of time. The 13 & 20 WPM tests are gone forever. And soon, the CW testing requirement will be eliminated completely. It's the will of the majority. It's evolution. You can whine, cry and carry on all you want about the CW testing requirement. It is going the way of the buggy whip, the Ford Model-T, dinosaurs, the carrier pigeons, and a host of other old, outdated, and unnecessary things of the past. Good Bye and Good Riddance.

I treat others the way they treat me. I treat you the way
you treat me. You insist on turning my inclusive statements
into exclusive straw men statements so you can argue with
them. You are the only one who can change that interaction.
We just had a civil exchange over on QRZ.COM where you didn't
misquote me for a change. That could happen here.

> No designer in his right mind would use such a lousy feed system to
> feed a pattern sensitive design like a Yagi antenna, they are barely
> acceptable as a omni-antenna.

I agree with everything you said about J-Poles in this posting
so you are apparently trying to set up yet another straw man.
One wonders why you feel compelled to try such a transparent
trick. When I disagree with you on one minor point, you react
as if I had disagreed with you on all major points. You really
need to learn the difference between "inclusive" and "exclusive".
My disagreement was inclusive of your point 1, not with anything
else you said. That's why I trimmed out everything else.

What I disagreed with you on is that common-mode current is
the same at two different points in a J-Pole system separated
by a 1/4WL stub feed system.

I'm thinking of changing my antenna. Currently it is an inverted V cut to 80, 40, 20, 15, and 10 meters, with one feed point. Due to the fact I'm renting and can't put up a beam, I've put the dipole on an old TV tower, which has guy wires, that is on the apartment building, the dipole is mounted so that it is approx. 2 ft away from the tower structure itself and I've tried to get it as far away from the guy wires as possible, so it is mounted above the wires.
My question is if I make another dipole using the same measurements and feed point only mount it so that it is at 90 degrees to the original dipole will I have any problems.

not the majority prehaps it is the will of and judgement of those that
are supposed to serve the bets interest of the people

the best interest of the people are served but ending code testing and
the code culture that has dominated it and sent it on a downword slide

not certain we can fix it with NOCode but it will be easier to try

659. Limited space horizontal loop for local 80M ops

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-16 16:04:41 UTC
From: ferrymanr <richardferryman@btinternet.com>
Message-ID: <zOCdnUqjSp8H_ifZRVnyiA@bt.com>
Source record: 56246

I live in the top flat of a building with a flat roof about 24' (7.5M) x 21' (6.5M) and 30' (9M) above ground. I need an 80M antenna to operate locally around the SE part of England. I have limitations on what I can erect.

I thought of a horizontal loop about 3' (1M) above the roof, possibly with 90uH to 100uH in each of the two side legs to help it resonate on 80M. I'm not very good at modelling and could not work out how I enter a reactance across the feedpoint to balance out the large negative reactance there. The FFT plot with EZNEC looks promising.

Can someone help me to work out how to feed this antenna and what reactance I should add at the feedpoint.

I have some options segarding the feeder and ATU. I have an SGS SG-230 ATU which I could mount near the loop or an LDG Z-11 that I could mount near the transmitter with a balun (I have several from 1:1 to 16:1) and balanced feed to the antenna. My preferred feeder is 50 or 300 ohm balanced as they are easily concealed or alternatively coax feeder and balun at the antenna.

Thanks for any help.
Richard (Dick) G4BBH

It is possible that someone could learn at 5wpm, not use it for years, and
still be able to use it, but I wouldn't want to bet my life on it.

More to the point is I can't magine a scenario in which CW would be the
only mode available, and that hams are about the only remaining users of
CW.

As it happens, I do think people should have to learn on a stick shift, but
I don't support code testing. If you can't drive a stick shift, you can't
drive my car, as every car I've had has had a stick shift and so will every
car I buy in future. OTOH, every rig I've bought has come with a mic, and
none of them came with a key. Now, I know you can get some QRP rigs that
are CW only.

The point is, there is a very real chance that it may be necessary to drive someone else's car in an emergency, or even just to help out. What happens when you need to get someone to the emergency room and the only car available is a stick shift? It's no good saying that statistically manual shifts are declining in sales, as there are plenty of us who will never buy an automatic.

OK, maybe you can say that you don't own a mic, and all the rigs in your shack are hooked up to a key (good luck on the local repeater!). What then is the realistic scenario where I will have to use one of your radios to save the world? (or even to save the next door neighbour) Doesn't seem to likely, does it?

I think this is the nature of the premise on which the original post was based.

Compare it to a similar situation, where a film camera user is debating a
digital camera user:

"If you came upon a drowning man, and you had to choose whether to save
him or photograph his demise, what kind of film would you use?"

A transmitter with no mic, no computer - just a transmit switch. Or
not even a transmit switch, but you can get to one of the battery
wires. Far fetched, but it could happen.

>and that hams are about the only remaining users of CW.

Boy Scouts? The military no longer uses CW - what used to be passed
by brass pounders is now passed digitally. Merchant Marine? Same
thing. Aero commo? Same thing, except for voice. I doubt any group
or service actually uses it these days.

Even those who tout digital modes - they want to buy an interface and
software and "be" on digital. Then they wonder why the signal they're
hearing, that sounds just like the digital mode they use, doesn't work
on their setup. Maybe because a PSK program won't decode SSTV?

Reminds me of the GPRS "exerts" who can't understand why changing the
"code" on their radios doesn't eliminate the interference from the guy
next door.

The anti-CW crowd wants no code and a written test you can memorize
the answers to. It's their "right" to be on the air, isn't it? Even
if they need 2 more clues to be totally clueless?

learn what you are tlaking about psk31 sounds very little like sstv and
most of the programs that can demolate it show you a spectrograhand
they look nothing alike

there is some time confusion in wether that sgnal BPSK 31 or QPSK31 but
the marvels of Windows wallo me to run the output of the sound card
interface to at least 2 program so it can be worked out

you just want to bash any ham that doesnot follow your morse fetish

it is our right and everybody else right that any restriction to our
access to public spectrum be "neccisary and proper" (one of 3 clauses
in the constitution that give the power to regulate the airwave to the
govet at all) otherwise the 10 reserving all right and power to the
sates or the people applies modifing that is the thrid place where the
consititution of US touches on this issue mby making the constitution
and the TREATIES made the supreme law of the land

according the Govt lost the POWER to impose Morse Code test on the ARS
unless it can be justified under some other powere of the Constitution

I find it interesting that the ProCode tes crowd has such disrespect
for that document

Source record: 56258

If you're only interested in 80m, get a good split stator loop tuning capacitor and put it opposite the feedpoint in the loop. Make the loop out of the fattest conductor you can find.

It'll basically be a big halo antenna for 80m. (maybe you could call it a magnetic loop.. i don't know if people ascribe a particular fraction of a wavelength limit on magnetic loop sizes)..You'll need a motor drive for the cap, because as modeled with 3/4" copper tubing and 3-j1200 ohms opposite the feedpoint, the 2:1 SWR bandwidth is about 15kHz.

Radiation resistance is 1.85 ohms or something like that, so you'd need low loss connections for all the wires and a welded capacitor... if you do it all right, though, you'd have a good efficient radiator for local communications.

Just a thought.

I think this would give you better performance than trying to inductively load the legs.

73,
Dan

Again you divert the issue. Will you never learn to
admit a simple mistake and move on? You were ignorant
of the definition of the word "rationalize" but you
are unlikely ever to admit it.

If you simply change your bad boy ways, the world will
be a much better place for all the rest of us.

Dan

Remember that this has to be a 'stealth' antenna as I live dead center in the town with a lady councillor opposite, the town council office 75 yards away and town hall about 150 yards away. This rules out low loss copper pipe etc. Most of the small 'magnetic loop' antennas are intended for vertical use which would also stand out like a sore thumb here. The advantage of the wire loop is that many buildings here have wire around the roof to deter seagulls, that means my wire would not be conspicuous.

When I modelled my 21' x 24' horizontal square loop with loading coils of about 90uH in each side leg I got a feed impedance of over 300 ohms but with -j5000 or thereabouts. The swr curved dipped nicely at 3.65 MHz to a manageable level if I used a 4:1 balun and 300 ohm line feed. I reasoned that as the natural loop resonance was between 20M band and 30M band I could link out the coils and operate those bands too, although that would means climbing up a ladder out of the rooflight rather more often than my old bones like.

One evening at 2330Z, KUT 90.5 covered WKAR 90.5 just long enough for me to hear KUT's station announcement! Texas is a long distance from Michigan.

It is important to note that the receiver was receiving WKAR (about 50 miles away) with a signal just a little above noise threshold because of a metal bulkhead in my new office. (I will have a better antenna before I am done.)

Dear Reg:

Patents are one of the things that makes a creative people great. In the Republic's Constitution patents and copyright are listed. Citizens have thereby a means to increase their wealth and provide employment while having available the power of the courts to protect their rights.

Not all lawyers are in favor of patents. A few, before they are cashiered, are against anything that inconveniences their clients, including laws.

At the other extreme, a few lawyers serving as judges have expressed disgust at the patent system, supposedly because it rewards the creative.

Please look for some Midwestern wine. It may assist you in recovering the common sense seen in your early work.

Warm regards, Mac N8TT

Oh Brother!
Reality check time: Why don't YOU read a bit about Medicare D?
Aging baby boomers are about to be screwed in ways they couldn't even
imagine.

Insurance companies entirely control Congressional debate and actually
write the rules. Most of Congress doesn't even READ what they're
signing on to.

O'Reilly, is that you?

Richard, I loved the "irony" comment, but there is nothing preventing the product of a piece of software from being used for something else. It's quite legal, and that's how "things" work.

Designing an antenna from a piece of software does not mean that the antenna design belongs to the person who writes the software. That would mean that the person who did the programming for a CAD program owns the rights to all the devices designed with it.

Look at the crappy no name coax and super cheap connectors on their
website before you decide anything. BTW, they have a very bad
attitude. One of their salesmen was on one of the sci.electronics
groups telling people off.

Dear Owen:

I was indicating a contract that was specific to the intellectual property involved. As you know very well: to have a contract, certain things must exist. Often with software, a meeting of the minds between the two parties is absent ("agreement" is inside of the software package or is too vague) or at least highly attenuated because of no chance to bargain. A license is usually a contract.

One of the best such agreements that I have seen is one that was used by WordPerfect. It was short, clear, and provided for the natural needs of both parties.

One of the worst was a proffered contract (for the purchase of a quantity of computers plus software) by a very major computer company that was long, convoluted, and essentially wanted your first born son it there were any deviation from the terms. At the same time, a contract was proffered by a then major Midwestern company. It was on one side of a piece of paper, clear, and said that as long as good faith was shown to comply with all of the terms, there would be no penalties assessed. The effects on comparing these two documents is obvious.

Of course, if the subject matter is lawful, parties may contract anything. However, the courts may not enforce some contracts depending on the nature of the clause at issue and the manner in which the contract was presented. The contracts least likely to have problems are those between parties of roughly equal bargaining power.

No matter what the issue is, I always advise clients to practice the golden-rule. Do not ask for too much. Do not promise too much. Be reasonable. Be clear.

I an not sure, but I do not think that I disagree with what you have presented.

I will be off to bed with one more example of what the law is and should be: the contract provisions of an insurance contract were being contested in court: the judge took judicial notice that a reasonable person would find a contradiction between what was on one page and what was on another page, thus that clause means whatever the plaintiff thinks it means. After that judgment, that type of contract became much more clear.

There is more to a contract than the words of the contract - sometimes.

I don't get it. A professional uses a piece of software designed for
non-professionals to design antennas, so the writer of the software
stops offering the software to the non-professionals? Seems backwards.

> 3. If I were to do a gratis optimization for someone today, that would

> doing so).

You are correct of course, but I don't understand the basic premise.

Let us use say, Mathcad instead of YO. Mathcad sells it's software with
the full knowledge that people are going to do things with it. Like
design things, and make money with them - or research dollars. It is
exactly what the program is designed to do. Mathcad's authors do not own
or have copyright to those things designed with it.

If the gentleman gets angry because people use his software, that is
his right, but it seems odd.

>>Hence the irony meter being pegged.

Source record: 56126

Dear friends

It is usually said (in my country) that the double bazooka antenna is
less noisy than a standard dipole.
I think that there are not good reasons that endorse such a statement
for noises coming from the far field (maybe it has some advantage with
near field noises or maybe because its frequency response cures some
pitfails of the associated receiver).

I have looked for information in the net about this topica but I have
not been lucky.

I suppose that you have treated this topic at some time. If you can
point me to a link to read about I would be very grateful to you.

Also if you can give me your opinion in this respect.

Thank you very much in advance

Miguel (LU 6ETJ)

Hi Mike,

I thought this topic had died a placid death - George Romero (another
PA resident) must have a hand in its continuance....

Anyway, a review of:
http://craphound.com/msftdrm.txt
might give some insight into how industry has created their own rights
from legislation called DRM (Digital Rights Management).

"Thinking" something is legal is not always "how" things work.

The video presentation of this written document, circulating through
Micro$oft for several years, is available at Google Video:
http://video.google.com/videoplay?docid=-1904758034876244745&q=cory+doctorow

You get to hear one of M$'s ringer lawyers try to pin Cory down, and
instead become roadkill. Cory rolled over him like a Lincoln.

Of course not. I've no doubt that a person can be sued for anything,
and nothing can prevent that.

Just feed it with ladder line. You will be able to match it with a tuner.
On 3.5 MHz, if you use a 30 ft feed line, you can match it with a shunt 12.6
uH followed
by a series 45 pF -- split series element, and double value for a balanced
tuner.
Follow it with a balun. With 100 W the voltage on the transmission line
varies between 1.9 and 2.7 kV peak. Transmission line and tuner loss totals
at
near 3 dB (Unloaded inductor Q = 200). Design of tuner trivial for higher
frequencies.
Any commercial balanced tuner should handle the load.

Regards,

Frank

I've thrown away better wire and connectors, but you can use whatever
garbage you want to.

Rotors are made for use on tall towers. There quickly reaches a point
in which rain rises as well as falls. Rotors have to be made water
safe from any angle so that shouldn't be an issue.

There used to be radio antennas that plugged into the wall outlets.
They had a three pronged connector, but only one side was actually
electrically connected, the other prongs were plastic. I am not sure
what they did to isolate the electrical from the radio, but the
antenna used the house wiring for an antenna extension.

This may be what he is looking for, something that coupled with the
electrical wires for a longer antenna.

In 'G' land what is the concern regarding public officials and radio antennas?

Here in W/K land public officials and radio antennas are not a concern. Public safety issues are a matter of local building codes. Private contracts, known as CC&Rs, are a problem.

It's surprising what can be done, with a bit of determination that you
are going to get on the air.

I know a ham who lives in a Listed building, which means he can hardly
even paint a door without consulting the local Council's Conservation
Officer. To make life interesting, he lives right next to the Council
offices, and there's a perfect view into his backyard from the
Conservation Officer's desk! Now that's what I'd call really living with
restrictions... yet he has still found ways to get out well on 80m.

(His antenna would be very unlikely to suit your situation, so there's
no point in describing it in detail.)

Always remember that you have rights too. With certain exceptions, most
UK householders have the right to put up a garden shed without asking
anybody's permission at all. A surprisingly large shed, too - with a
pitched roof, the ridge could be up to 4 metres high.

Check how that would apply to you. And then, if anyone objects to you
using a 4m high vertical loop, ask them if they'd seriously prefer that
you build a whole big shed around it?

>The advantage of the wire loop is that many buildings here have wire
>around the roof to deter seagulls, that means my wire would not be
>conspicuous.
>
That would certainly be another option to explore; but whatever you do,
be sure to make the best use of all your rights.

I tested an IAC double bazooka, and it is no different than a regular dipole. It has very slightly less signal level, and very slightly more bandwidth. Not enough to worry about. No measurable difference in noise.

I would transmit on an efficient short vertical, and use a magnetic loop
on Receive. For that matter any low noise receive antenna like a Flag

or K9AY. I would also look at something like the Welbrooke Active loop. I wont get into the debate of "magnetic" and noise! Just go to Welbrookes web page and read some of the reviews from a EMC expert on noise and comparing the Welbrooke to 20,000 Dollar R&S EMC antennas E and H plane antennas.

If W8JI and others can work DX on 160meters from an efficient mobile antenna, you should have no trouble getting out. There was a guy on 80 meters from the west coast K6MB who used to beat stations with dipoles in the 80 meter DX window with a coil loaded mobile antenna!

Dont believe all the high angle low angle nonsense, the difference in real terms amounts to one deep fade. I would never feel at a disadvantage running a vertical versus a low dipole.

There was a interesting article in QST by Some PA hams who used a R&S super resolution DF antenna and measured incoming arrival angles across Europe, oh how i would like to have one of those setups! They use cross loops too.

There's a world of difference between technical electronics knowledge
and ability to decipher code. One has absolutely nothing to do with the
other. FWIW, I don't even have a ham license anymore. I don't care
about the code, whether it lives or dies. If you enjoy brass pounding,
then do it.

Just don't equate that ability with another that is not even slightly
related.

Ugh. Those things. "Turn your entire house into a gigantic
television antenna!"

These devices usually just couple one of the wires in the outlet to
the antenna lead, using a small high-voltage capacitor. Component
parts cost was a few cents, plus the cost of the plug, and (usually)
some intricately-shaped plastic case meant to make the device look
sophisticated. The case probably cost more than the guts, and the
advertised price was far greater than either.

From all I've heard, they generally gave poor performance for at least
two reasons:

- A house's power wiring is an excellent vehicle for RF noise and
hash... harmonics from power-supply rectifier, broadband impulse
noise from any AC motor with brushes, and so forth. Result: lots
of static in the picture.

- Multipath. The house wiring is of a complex shape, much larger
than a typical TV antenna. The TV or radio signal is likely to be
picked up by several different portions of the wiring, which will
mix (with varying amounts of time delay) at the coupler. Result:
a ghosty picture.

To paraphrase a Monty Python sketch concerning a particular Australian
table wine: "This is not a technology for using. This is a
technology for laying down and avoiding."

That sounds like what I was describing. I had an experience once where there was a drop cord hanging in a loop shape from a power line that lit up a boat pier about 100 feet long or so. When I put my shortwave radio near it, I had tremendous reception on MW or SW. I didn't need to even use the antenna on the radio. I figure there was about 300 total feet of wire the way it was run. Had a great night fishing and listening to SWB.

Spoken like a true appliance operator.

If there is any crying and whining after CW is gone, it will be by phonies
wondering why their bands sound like CB.

Getting rid of CW is like choosing the kind of film.

Ham radio is drowning and the anti-code hams want us to think tossing it
bricks will make it float better. Dumbing things down is never an
improvement.

Considering that someone with absolutely no knowledge of electronics
can memorize enough to pass the test in about 8 hours, there's no
longer any real test of anything but the ability to memorize.

>FWIW, I don't even have a ham license anymore.

Then, as the courts would say, you have no standing in the matter.

nope he has full standing he is an american that means the FCC is
suposed serve not the ARS but the people of the USA.

the problem with you procoders is that you think the ARS owns the
bandwidth not the poeple of the USA

No can do Cecil.
That goes back to his high school days and it only got worse.
The best way is to state your wisdom against his and let the in-know judge and blind followers, worship. Too bad, but that is the reality. Makes Freaktenna look like a school boy. Add to it pretending to be an engineer and you get the picture.
He will never admit to be wrong (never happened yet), if he realizes he was wrong, he will just go QRT on the subject for a while and then reemerge shemelessly as guru on the subject, without giving credit where is due.
"Discussions" turn into obfuscating the subject, mumbo-jumbo and end with personal attacks and ridicule. Oh, wait, it culminates with threats of lawsuit.
Such a shame, so many decent and knowledgeable people get turned off by this crap and ham community misses great resources.

"Seen" except for special needs. And those that do special needs will
likely be making millions. There will be about 12 of them that make it,
and thousands that don't, but wish they could.

I know quite a few in the photo biz, and film is, to put it very
bluntly, dead.

Eliminating a requirement is dumbing things down. But no one would
expect you to be able to understand that.

>you are
>indeed you advocate dummbing down radio and giving hf only to the
>unintelgent

That's YOUR stance - giving HF to those not intelligent enough to
actually learn things.

For most people, he written test is also a test of the ability to
memorize. Just show most hams licensed in the past 10 years a
schematic and ask them to find a component by function. "Knowledge of
electronics"? It would be funny if it weren't so sad.

In 1953, as a sophomore in high school, I didn't know any
electronics and was therefore forced to memorize the ARRL
License Manual in order to get my Conditional license.
People like me have been memorizing License Manuals for
more than half a century.

Rules and regulations are just an exercise in memorization also. They require no knowledge of electronics either.

The CW text requirement is like the requirement for a foreign language requirement for some college degrees, it rounds out the amateur skills.

an improvement over the drivel most of the procoders are posting
although the analogy streches a bit if I ask what college in the wolrd
has a requirement for one foreign lang and only one

did you submit it in your coments to the FCC?

all in all not bad

Message-ID: <12bone4ol8me4a2@corp.supernews.com>
Source record: 56084

All antennas consist of conductors which have current conducted to them from sources and induced in them by coupling to fields from other conductors or other parts of the same conductor. These currents create fields. Ground plane antennas work exactly the same as all others. In that way they're simple to understand.

Yes, you can view it this way or that, with various degrees of accuracy and inaccuracy. The problem is that people begin to believe that the alternate views are really what happens, rather than attempts at simplifying and understanding things. Before you know it, you've got mirrors, "ground" high above the Earth, impossible reflections, and other dubious concepts which end up leading people farther and farther from really understanding the basic principles involved.

Those are called grid squares. The world is divided up into squares, each being 2 degrees of longitude by 1 degree of latitude. Search google on "Maidenhead Grid" and you will find many pages that explain it. On VHF, we try to work as many grids, world-wide, as possible. If you listen on 6M (or any other VHF and above band), you will hear most people exchange grid information at the beginning of the QSO...something like "I'm in Fox November 02" or "Please copy Echo November 45" It's kind of like State or County hunters on HF...

My amateur radio license, obtaining by memorizing the ARRL
License Manual in 1952-1953, was the catalyst that caused
me to seek and obtain a EE degree later in 1959.

The point is that an amateur radio license is a learner's
permit to exercise certain privileges during a lifetime
of learning. It is a permit, not a graduation certificate.

Note also that each grid square are also subdivided into 2.5 minute by 5
minute sub squares. They are given 2 more letters. Thus the full grid square
for my QTH is FN10bs.

I use a digital for my family memories type shooting.

I use FUJI roll film in 120 size for my serious MF work. It is either Fuji VELVIA for transparencies or NPH for formal portraits.

In either case, digital or film, they have nothing to do with ham radio in general or CW in particular.

CW is!

757. Length & number of radials

If you are considering a new vertical antenna, instead of guesswork
and copying somebody else's un-thought-out efforts, download program
RADIAL_3 from website below.

The program assists with choosing an economic length and number of
shallow-buried ground radials. It takes a new look at how radials work
by considering them to be lossy, single-wire transmission lines,
open-circuit at the other end.

RADIAL_3 is a self contained file, 55 kilibytes. Easy to use. No
training needed. Download in a few seconds and run immediately.

Now, I hope I get some reasonable responses to this (along with the usual crap).

I recall a toy my kids used to have and it made think of similar technology to creating a "deployable" antenna.

In this particular toy, a series of slightly S-shaped plastic bars were linked together such that the entire ball could be collapsed into a spider-like ball with all bars positioned radially from the center. When pulled apart, all bars positioned circumferentially in a bucky-ball-like sphere. I thought that was cool.

Has anyone come across an antenna design with similar mechanism?

I can envision a loop antenna that could be deployed after dark, for example. It could be rotatable vertically or stationary horizontally.

I have more trouble visualizing a planar version but probably possible.

I link this in my own mind with SteppIR technology, in which the resonant freq length is continuously variable...varying circumference as the diameter of the loop is varied.

Perhaps someone can respond with an open mind. Plenty of reasons this idea is impractical but I thought it would be fun to speculate.

It's a cool idea. Not sure the 2D version can be made stable, that is in the 3D version all of the nodes are constrained enough by the links around them that there's only one position they can be in relative to each other.

Maybe you could build a hoberman-sphere antenna by having some conductive parts and some nonconductive ones. That is, have the full sphere mechanically but only a small fraction be electrically active... it'd sure be an amusing antenna.

A hard part with any antenna that physically changes shape and/or size to get a different resonance (including the SteppIR!) is that it's hard to envision a system that doesn't require sliding electrical contacts somewhere, and it's hard to do a sliding electrical contact that has low resistance... SteppIR gets around it by using totally enclosed elements and beryllium copper which is good for wiping contacts.

That's certainly not to say it can't be done, just takes some thought and realistic expectations about performance. Let's say you have a 200 ohm feedpoint impedance for a continuous copper full wave loop. If you have 1 ohm of resistance at every joint in an loop antenna that has 200 joints, you're down to 50% efficiency once you match the 400 ohm feedpoint impedance that results.

If you can take that down to 0.1 ohm per joint, then you're better off...

If you have an antenna that has geometric-looking linear loading, you might have to deal with an irate Fractenna too... dunno.

Seriously, though, as long as you can figure out how to ensure low resistance, reliable electrical connections through mechanical joints, all sorts of adjustable-length antennas would be possible.

How about a slinky-like coil that is attached to the undeployed ball as
a tightly wound coil but then stretches "flat" with increasing
circumference. So, thereby decreasing inductance with increasing size?

From: David <nospam@nospam>
Message-ID: <wMWdnbFBmIgbpCDZRVnytw@bt.com>
Source record: 56101

The vertical element is connected to the centre conductor (RF live). The radials are connected to 0V on the transceiver.

If only the vertical is connected, the antenna still radiates although not as well. If only the
radials are connected, the antenna does not radiate because the radials are connected to 0V and not a varying voltage.

With both vertical and radials connected, the vertical element radiates the wave. The wave is reflected by the radials as boundary condition of Maxwell's equations. The reflection induces a current in the radials. This current has a standing wave on it.

Do you think the above is correct? All parts of the antenna form the impedance. Without radials, the impedance is poor and the vertical element does not radiate well.

Other explanations say that displacement currents go through the air and terminate on the radials. The displacement currents then becomes conduction current in the radials. Displacement current is another anomaly with electromagnetic theory.

I notice that two people have simulated the vertical antenna with radials using EZNEC, and obtained different results. One simulation shows that the radials radiate, the other shows that they do not.

>The vertical element is connected to the centre conductor (RF live). The
>radials are connected to 0V on the transceiver.

No. They're connected to the shield/braid of the feedline. There's
no assurance that this point will be at "0V" with respect to anything
in particular except itself, and in particular it usually won't be at
0 volts with respect to the transceiver's chassis / output jack
(except perhaps momentarily, twice per RF cycle).

>If only the vertical is connected, the antenna still radiates although not
>as well.

... because the outside of the feedline will tend to act as a
poorly-tuned radial/counterpoise.

>
>Do you think the above is correct?

Not really, no. It's a mistake to think that the radials "are
connected to 0V and not a varying voltage". You're falling into the
trap of thinking that "ground" is some sort of magical "zero volt"
reference which is the same everywhere. That isn't true even at DC,
and it's certainly not true at RF!

> All parts of the antenna form the
>impedance. Without radials, the impedance is poor and the vertical element
>does not radiate well.

The vertical element radiates very well indeed... it'll radiate all of
the power which is fed into it, except for a small amount of loss.

The problem isn't that it doesn't radiate. The problem is that it's
difficult to feed power into it, much of the time.

Hi Dave,

Your statements above show a serious problem with understanding the
operation of antennas.

The radials are not potted plants merely arranged along the ground (or
in the air) to give a sense of symmetry and balance.

You would go further to engage more in dialogue rather than simply
posting statements. Much of the utility of radials has been
discussed, revisited, and rehashed to no apparent effect against what
you offer above. The last sentence is outrageously wrong for any of a
number of reasons (or proof of some pretty stupid simulation).

Agreed, the centre junction of the radials is not always at 0V. Current flows along the coax braid on the inside, meaning that the inside part of the coax braid and radials junction can be any voltage. The radials have a voltage gradient along them because of the standing wave. Because the return current flows on the inside of the coax braid, it is normally safe to touch or go near the outside of the braid. For permanent low installations in a public area, coax should be used instead of twin feeder. The fact that the return current flows on the inside of the braid gives coax its shielding properties.

Decreasing inductance will raise the resonant frequency as increasing
size lowers it. One will be faster than the other, so maybe you can
get some tuning range out of it.

Hard to say how much without trying it, but you do have competing
changes in the wire if you do that.

One thing to think about: A reel of wire coiled up at the high
voltage end of an antenna where little current flows adds very little
to the electrical length whether or not it's insulated (insulated
intentionally by plastic or unintentionally by oxides...) The
inductance of the coil formed is fairly inconsequential because almost
no current is flowing through it.

I said "by function". Not "locate the resistor", but "locate the
balanced modulator circuitry".

You used to have to draw a few schematics on blank paper - no hints.
Now you have to be able to identify a resistor. Big deal - that
should take all of 3 seconds to memorize. Memorizing which side of
the heart sends out the oxygenated blood doesn't make you a cardiac
surgeon.

Hi David,

In isolation, this statement offers nothing at all, unless, of course,
you are talking about an unexcited system. The notion that 0V
inhabits some greater portion of the antenna, or its radials, or its
junction is a strange concept to its normal operation.

David, AE6EO, has similar concerns that you are presenting what I
would call a naive representation of radiators.

>Current
>flows along the coax braid on the inside, meaning that the inside part of
>the coax braid and radials junction can be any voltage. The radials have a

In that sense, 0V does reside at some favored points, but this is not
an explanation of anything.

>Because the return
>current flows on the inside of the coax braid, it is normally safe to touch

Is this germane to a particular point? Again, these are simply
statements, and they appear unconnected to any kind of dialog.

I've used a couple programs (vertload.exe and I think LODI) to design
a shortened, single band dipole antenna for 30m. Specifically I'm
interested in 10.149MHz.

The result is:

--1m wire--[~34t 1.5" form 2" long, ~24uH]----2m wire----[center]--...

The center would be a 1:1 current balun, twisting the wires together
and then taking 10-12 turns on FT50-61 (or if that won't fit, fewer
turns on FT50-43).

The predicted resistive input impedance is 22 ohms. Vertload is just
simulating half the antenna (with 0 ohm ground loss) so its match info
is not useful. The other program called for a ".71uH matching coil"
for 50 feed, which I assume is to cancel a calculated -j45 reactive
component??

I would like to pre-calculate an approximate match to Z=50ohms which
I can put directly at the feed point and shrink-wrap with the balun.
Is there a way to do that, or is it too touchy to do without measuring
the actual antenna?

My simulation indicated that the horizontal radials radiate
hardly any horizontally polarized radiation, unlike a horizontal
dipole antenna. But there's no way for me to separate the vertical
radiation of the radials from the vertical radiation of the
monopole.

However, the method of moments will indicate why two in-line
segments carrying the same current in the same direction interfere
constructively while two in-line segments carrying the same current
in opposite directions interfere destructively.

If you were within 20%, you would be lucky. Best to fine
tune it before shrink-wrapping it.

Well, let's see. The radiation resistance is about 9.2 ohms, so the efficiency is about 42%, or 3.8 dB down from a 100% efficient antenna (a full size dipole is nearly that). With that much loss, the bandwidth will be about 180 kHz, so you might be able to get by with a calculated network. I'd measure it, but making a good measurement isn't simple at all, so you're likely to do better working from model results than measurements unless you're experienced and have good equipment.

This is not very clear, you say 22 ohms then seem to say it is half
the antenna, is the input resistance to the dipole ~22 ohms or ~44
ohms?

Whichever, it is a relatively simple matter to calculate the
components of an L match, where you detune the dipole to get a small
capacitive reactance and shunt the feedpoint with a coil to match to
50 ohms.

If the R component is around 44 ohms, you need to detune the dipole to
about -18 ohms of reactance and shunt the feedpoint with about 2uH.

If the R component is around 22 ohms, you already know the answer, you
need to detune the dipole to about -25 ohms of reactance and shunt the
feedpoint with about 0.7uH.

An adventurous approach. You seem uncertain about the calculated
design, doesn't that suggest trying it before committing it
permanently?

Dan,

Thanks for your input. I'm just free-forming ideas here.

I would think that the tightly coiled position would only be for
storage, when not used.

But, think about a 2 meter diameter sphere, the circumf would be 6.28
meters, divide that by 30 "loops" and
each loop is about .21 meters per loop and having a diam. of 6 cm. i.e.,
a 30 turn coil, 6 cm wide. More "loops", smaller diameter coil.

When opened completely, the circular loop is "flat" and 6.28 meters long
with a 2 meter diameter.

When half opened (diam = 1 meter), the loop is partially coiled. How
many turns would that be? I don't know how to solve for this.

How would I fashion an approach to calculate resonance for any given diameter under these circumstances?

Yes, I'm probably not the brightest bulb in the pack, but it's still fun to speculate...this is an AMATEUR group, afterall.

> ??
>
> Dan
==========

Dan,

The up-and-down change in efficiency versus radial length is due to resonance effects. With a high value of soil resistivity of 500 ohm-meters resonance is not completely damped down. This is also indicated by the relatively small decibels per 1/4-wavelength figure.

As radial length is varied the input resistance of the 96 radials changes. Look at the wavelength of 1 wire figure. It will be seen that length passes through 0.5 wavelength resonance at 6.0 metres. It passes through 1.0 wavelength resonance at 11.6 metres. At both these lengths the input resistance is at a maximum and so efficiency is at a minimum.

At 2.9 metres and 8.8 metres the radials are in 1/4-wave and 3/4-wave resonant and the input resistance is at a minimum and efficiency is at a maximum.

Vary length while watching the resistive component of input impedance to see what happens. It's highlighted in red.

If you reduce soil resistivity from 500 to 50 ohm metres the resonance effects will probably disappear and the decibels per quarter wavelength will increase. All resonant effects will have disappeared when radial attenuation is about 18 or 20dB or greater.

The effects of resonance are not observed so well when frequency is varied because so many other things change as frequency is varied over an octave or more.

Resonant effects are much greater at 20 MHz and above with very high resistance soils such as desert sand. The radials then behave very similarly to the elevated variety.

I trust your confusion has now gone away. ;o)

When I use vertload.exe to model one HALF of the dipole, I get a radiation resistance of about 12 ohms plus wire loss of about 1.5 for an input resistance of 13.5 ohms. I am assuming that if I put two of these shortened quarter-wave verticals back to back I get a dipole with performance (but not radiation pattern) similar to the quarter wave vertical over a near-perfect ground.

[and I'm going to stick with those numbers and ignore the other program for this post]

> Whichever, it is a relatively simple matter to calculate the

> capacitive reactance and shunt the feedpoint with a coil to match to
> 50 ohms.

Ok, so the math would go like this:

At 10.149MHz, my input resistance would be 13.5*2 (two verticals back-to-back) or 27 ohms. It's got no reactive component at all because it's tuned perfectly.

So if I added -25j capacitive reactance, for example with about 620p in series with feed point, then transformed the series impedance Z=27-25j into parallel admittance Y=0.02+0.018j, then I see my equivalent parallel resistive component is 50 ohms (ok!) and I am left with a -54j parallel capacitive reactive component, which I can cancel with a 54j parallel inductive component, which is my ~85uH inductor across the feedpoint.

Now, to save money on capacitors, I could alternatively detune the dipole by shortening it until it was Z=27-25j at my 10.149MHz center frequency, and then shunt as before to get the same effect. Is that right?

I guess I also don't understand what happened to my resonance point when the changes were made to a tuned antenna to produce the desired feedpoint impedance.

> An adventurous approach. You seem uncertain about the calculated
> design, doesn't that suggest trying it before committing it
> permanently?

Well, I know relatively nothing about building antennas, and I have no relevant test equipment (except an SWR meter, but no transmitter as yet) and no antenna tuner. Getting the antenna built was a side project while I wait for transmitter parts. Perhaps building a quick and dirty L-match would be a better use of my time!

Resonance of the "radiator" is not a prerequisite of performance. The
changes that you are likely to make to introduce -25 ohms or so of
reactance will not impact the losses in the radiator much or the
pattern.

With your guestimates of the starting point, why don't you wind the
0.85uH inductor so that you can adjust it a little, build the dipole
and loading coils and tune the dipole for least SWR (length or loading
coil adjustment). If the least SWR is not low enough, tweak the 0.8uH
inductor higher or lower and repeat the process, and follow the clues.

Hi Ben,

You are on the right track. Put up the tallest stick you can, plant a dozen radials around it of approximately the same length, and match it with a gamma match. You don't really stand to gain much by making it any more "efficient."

Actually the Code that Sam developed is completely unlike the code we use on radio. What is tested for is the "International Morse Code" Sam's code was click based and radio is beep based.

DGN,

The Modern International Morse Code was invented by
Friedrich Clemens Gerke in 1848 and first used for the
Telegraphy between Hamburg and Cuxhaven in Germany.
After some minor changes in 1865 it has been standardised
at the International Telegraphy Congress in Paris (1865),
and later normed by the ITU as International Morse Code.

>

Actually that is not correct.
Within the original meaning of CW, the Titanic used a CW transmitter.
It was not a spark transmitter, the rf energy was produced by an alternator
which provided 'continuous' rf power, hence CW. The output was not a damped
wave that a spark transmitter would produce, but an interrupted 'continuous
wave' (from the alternator).

How high is this antenna and above what kind of ground?

For 15m high, I get values of 21.21 microhenries and 9.85 picofarads
across the feedpoint (you could make that out of a short coax stub). SWR
would be 1.82 to 1 on 50 ohms, though. That could be improved upon by
altering the length of the outer wires a bit and tuning the capacitor to
match.

Short loops do not work very well with rotating parts in them. Mainly
because such rotating parts have rather large resistance compared to the
radiation resistance of the loop itself. It's bad enough if you use
some pure conductor like the shield of LMR-400 coax or heliax.

Now as an unfoldable section ABOVE a center loading coil, the idea might
work.

Very nice. But one thing I have noticed is that radial effectiveness
begins to fall off at a distance from the antenna very similar to its
height. This seems to be due to capacitive coupling between the top of
the antenna and the radials. Does your algorithm take this effect into
consideration?

I modelled an antenna I used to use and the results did seem consistent
with the behaviour, though. Actually I used to use two of them, and
actually had a gain over a single perfect-ground antenna. Not a LARGE
gain, but still, useful. More useful was the fact that I could control
the take-off angle and pattern to the point where the antenna actually
sounded about 10db louder than a low dipole--at distances of 1000 mi or
more.

Sam's original equipment used ink and scrolling paper to
record the dots and dashes because he didn't think an
ordinary human being could distinguish between the sound
of the dots and the sound of the dashes. He was wrong.
Human operators quickly discovered that they could distinguish
the difference between the down clicks and up clicks and
therefore distinguish the dots from the dashes.

It is true that Sam's "American" Morse was different from
"International" Morse in about a dozen characters but both
used dots and dashes. Still, more characters were alike
than were different.

The term "lid" may have originated from newbie Morse operators
laying a lid on top of the relay receiver to make it easier to
distinguish the dots from the dashes.

> The one long counterpoise is several hundred feet long.

At least three symmetrical radials are required for a
close to omnidirectional pattern when the radials are
elevated by an appreciable amount. The horizontal radiation
from symmetrical radials tends to cancel due to destructive
interference thus adding constructive interference to the
vertical radiation pattern. So the gain and efficiency are
also affected. Resonance may not be the only consideration.

Please note that I didn't say ordinary human beings could read
telegraph code. All I said was that ordinary human beings could
distinguish between the sound of a dot and the sound of a dash.

I think that's a pretty safe assumption with "ordinary" in the
sense of an average human possessing average hearing abilities.
I would bet that a dog could even be trained to distinguish a
dot from a dash.

I sure wouldn't fully trust a NEC based program for buried wires, let alone a program someone just threw together without any verification at all. This is especially true when the answer looks so weird. Standing waves on a wire in contact with soil making efficiency go down as the wire length is increased? Give me a break!

I seriously doubt any vertical antenna would be even close to 93% efficient with 7 foot long buried radials.

A precise looking answer that gives us a warm fuzzy feeling makes the answer a good one, no matter how wrong the answer is.

That's true.

But there's no way for me to separate the vertical
> radiation of the radials from the vertical radiation of the
> monopole.

That's not true. You can look at the overall pattern and look at the effects on patterns with different radial systems to get an idea what direction and angle the radials might significantly radiate.

Hence the pattern distortion as elevation angle is increased and decreased from an elevated or freespace vertical with two (or even to a much lesser extent four) radials.

From: Win <w0lz@winlyn.us>
Message-ID: <1shsb291lfah62ofblabrjc6089l0d125u@4ax.com>
Source record: 56052

I recently put an A/B switch between my FT-1000 MPV and my IC-746 to make comparisons between receivers. I would now like to leave this A/B switch in line, as I would like to use one radio for CW, and the other for SSB. The IC-746 is known for having a sensitive front end (easy to damage). I am running 200 watts from the FT-1K. The A/B switch grounds the unused port. My fear is that the FT-1K will damage the front end of the IC-746, even as the IC-746 port is grounded.

I have to assume, no matter how diligent I think I will be, at some point in time, both receivers will be on the same band, near the same frequency.

Is it probable that the grounded loop to the 746, being 1/8 inch from 200 watts, will survive without damage?

Has anyone operated an IC-746 under these conditions?

Win, W0LZ

I have an IC756 and FT847 going to the same (HF) A/B switch. No problems.
You will want to do this on the input side of any amplifier.

I don't know about boundary conditions, but when I use this program to evaluate the following system:

3.62 Mhz, 18.3 meter height (simulating an inverted L with 25.4 ohms Rrad)

Resistivity 25, Permittivity 25

2mm radials, 4mm antenna wire, radials 1 mm depth (actually #14 insulated wire, stapled to the lawn and sinking in gradually)

..it shows my predicted efficiency with (26) 50' long radials to be about 90%.

My measurements indicated I am getting about 88%. Pretty good agreement.

What causes me to cringe, is that the program shows that I can reduce the length of my radials from 16.1 meters to a little over 4 meters without losing ANY significant efficiency. Given everything else I've read over the years, that just seems to be way too good to be true.

Now, I suppose I could rip up my 26 radials and shorten them all to about 5 meters and re-measure my efficiency, but that's a LOT of work (and it's 97 degrees out with a dew point in the mid 70's). Not going to happen.

Here's the kicker... I have 1000' of remaining wire to put down (and I am going to add it). If this value of 4 or 5 meters (15 feet, let's say) is even remotely correct, I can put down 66 more radials (although they would be interlaced with the existing 26 longer ones of 50' each).

Using my initial length of 50', I can put down 20 more radials, giving me a total of 46 radials 50' long.

Reg, you program seems to be telling me that I would get the maximum benefit by putting in 66 more radials approximately 15' long, and that installing them at 50' would be wasting 35' of wire per radial, and reducing radial coverage as well.

So...what should I do:

1. Add 66 greatly shortened radials (accepting Reg's program as correct)

or

2. Add 20 radials, maintaining my 50' length that I originally used.

I look forward to comments.

Good thinking, Richard, as I may try to get this inverted L to do 160 in the fall/winter by adding a trap to the 80m inverted L and extending the wire for 160m resonance.

Incidentally, over the weekend I tried to add a 40m wire parallel to the 80m L...it was a complete failure. (I used a "fan" approach with 6" standoffs for the 33' vertical wire). I thought I might get 2 fer 1 at the feedpoint, but it just didn't work worth a darn. Very low noise level, signals were significantly weaker than my Carolina Windom 80 (on 40m) up 42'. I did work a few DX stations with it, but just not up to my expectations. A properly performing 40m 1/4 w vertical over very good soil and a full radial field as described in my prior message should have been outstanding. It wasn't. It was very hard to tune, showed no better than a 3:1 VSWR at resonance, and was only marginally better on a very few signals between sunset and sunrise. Very disappointing.

So...your suggestion for 160m is a good one. I could do a trap pretty easily. If I wanted to try 40m with the same feedpoint, I could put a parallel tuned circuit at the feedpoint and run the 80m inverted L as a 40m half-wave. Of course, this requires switching at the feedpoint and I'm not sure I'd bother. I also have to get a 1.9 uH coil and 250 pf variable cap to do the tuned circuit (per ON4UN's Low Band DXing Handbook). I found an acceptable cap for 40 bucks and coil stock is readily available. I just have to get motivated and work out the relay switching.

I wondered if I could EVALUATE the effectiveness of the 80m inverted L on 40m as a half wave, by temporarily taking an antenna tuner with wide range (T-network matches almost anything) out to the feedpoint and matching it there. If it hears well, and works ok at 300w (tuner limit), then it might be worth investing in the coil/cap/relays to switch a more standard high-Z feed in and out. What do you think?

Thanks for your input.

Hi Bart,

Having noticed your question went unanswered, and that you have a very
curious arrangement that begs discussion:

Yes, the fanned out tuned radials are necessary for resonance (or at
least reduce interaction during the tune process). This is because
these types of antennas are especially designed for these very
requirements. That, or ground mounting that allows the proximity of
earth resistance to wash over the inherent Q that forces attention to
radial lengths. You have chosen to mount up high, and that demands
that attention to those lengths. This much should already be apparent
with a SWR meter reading.

Alternatively, this curious several hundred foot long "counterpoise"
may give some relief to a raging SWR meter, but along with that comes
unintended consequences. Given this "counterpoise" is easily ten
times bigger than the "antenna" you may note that my usage of "quote"
marks is to denote another irony. You have, in fact, a horizontal
dipole with a vertically oriented, tuned, short half. The 5BTV is

more the radial than it is the antenna.

This is not to say that it affects performance poorly. In fact it may be a boon, but it certainly isn't going to be performing for the reasons you might ascribe to it. Let's just say this is an example of Ham Luck which proves radio is fun for not having critical requirements. Any pretense to gain and efficiencies being obtained through carefully balancing this "counterpoise" are sheer fantasy. You could as easily pull down the 5BTV, leave the "counterpoise" connected to the mast, and drive the mast to the same advantage. (Or leave the 5BTV up there as a sort of top-load.)

If you want to resurrect the 5BTV's dignity that is now in shreds, follow the manufacturer's recommendations for installing tuned radials for each band, and attached at the correct point. Unfortunately, there's no promise of any increase of performance, but others may offer reports that confound my advice.

The configuration of 35ft vertical + 35ft (or so) horizontal worked well for me on 40m at the old QTH, and was quite effective on 80m DX. For 160m, I added a 100ft loading wire to bring the total length up to about 130ft, and that configuration doubled as an end-fed half-wave for 80m short-skip.

Having a QRO auto-ATU made band changing easy, so it wasn't necessary to resonate the antenna on any band. However, the quarter-wave resonances on 80m and 160m could have been trimmed to length.

Coming back to the difference between the 40m vertical quarter-wave and the bent half-wave, I compared the bare 35ft mast and the same mast with the added loading wire and didn't find much difference. For DX, the bent-half-wave should have been down on the quarter-wave (because some of the radiation was being wasted at high angles); but in contests, both antennas seemed to work the same regular DX stations. The bent half-wave was louder for short-skip, which meant more QRM at night, but made it easier to continue making low-point contacts during daylight hours.

If you use an 80m trap, the antenna could still work on 40m but the horizontal section would be way over-long. Unless rapid band changing between 80m and 160m is a priority, I'd suggest you use a physical disconnect at the end of the 35ft horizontal section. (My setup made it very easy to loosen a rope and lower the connection into reach, so I used simple banana plugs, with snap links to add either wire or plain cord.)

Hi Hasan,

I must think that you were only slightly off in length, and that the
proximity, even at 6 inches, is still proximal.

>Very low noise level, signals were
>significantly weaker than my Carolina Windom 80 (on 40m) up 42'.

Not unlike many similar reports.

Some of those same reporters suggest split operation where the
vertical is the radiator and a high horizontal is the receiving
antenna.

John-

Its hard for an old fogey like me to follow the details of this thread. To start with, I'm not familiar with the toys mentioned. Yet this type of discussion is conducive to creative thinking. You start with something that may be a bit fantastic, and end up with a good idea.

My idea of a "deployable" antenna is a metal tape measure. Only it isn't a new idea. Many years back, Telex Hy-Gain produced a Model 18TD, Tape Doublet, 10 thru 80 meters portable antenna. There was also a military version, the Hy-Gain HA4000. See a discussion at http://www.qsl.net/n2ckh/HA4000.htm

However, I still think that with only the vertical element connected to the centre conductor, the vertical element radiates although not very well. With only the radials connected to the outer braid, the radials do not radiate. The RF live of the transceiver is normally connected to centre conductor, and the RF ground side (the 0V side) is normally connected to the braid. The outer of the connector on the transceiver is possibly connected internally to the case and mains Earth.

Hi David,

Only the slimmest margin of this comes close, and not enough to
explain anything. 0V, ground, live, dead, hot, cold, or whatever you
want to call it has long since disappeared from the scene at the other
end of a cable or twin lead. Radials do not mimic these terms even if
the illusion of continuity suggests otherwise. There is no "rf side"
nor is there a "ground side" to appeal to. Such distinctions are
reserved for very untechnical allusions.

Dear friends:

Thank you very much for your answers.

First of all: I agree with you, but my agreement is inductive, not experimental because I have not made my homework with that antenna...
.
I knew the excellent article of Walter Maxwell, I am a fan of Maxwell, (both Maxwells) from their famous article "Another look on reflections"

But do I think: is it possible that all those friends that are enthusiastic of the bazooka are affirming foolishness? They say: -With the bazooka we listen stations that we don't with the plain dipole, and this affirmatiotn point to a better SNR...

I think that it must have something true behind so many similar statements. In the radio club of my area they say to have compared one against another with clearly favorable results to the bazooka.

I thought...: A plain dipole is not a monoband antenna, it is, in fact, a multiband antenna, it receives all the frequencies. But do let us imagine a plain dipole that had connected on its terminals a couple high Q tuned circuits. That system it would be really "monoband"... then, if we connect such a system to a poor receiver Would not it improve the reception perhaps?, eliminating by that way possible saturation sources or intermodulación noises.
Such a system, empirically it would seem a practically "more silent antenna" and it would explain, perhaps, the some results obtained by the colleagues. I say this because it is said that the bazooka possesses a syntony effect that transforms it into a true monoband device (I am not sure of it).

It is only an arbitrary example of possible alternative explanations that, without violating the fundamental principles, can be compatibilized with the experiences of so many colleagues that sympathize with this antennas(some of which deserve my technical respect).

I thank all your answers but I continue to the search of some explanation that endorses all the facts, just as the formidable article of Walter in reference to its bandwidth...

I am for sure some of you will be able to help me to find a convincing explanation.

Thank you very much in adavnce

Back in the olden days a BA degree focused on art, humanities, language, sociology, etc.

Back in the olden days a BS degree focused on math, more math, physics, chemistry, biological sciences, etc.

The basic difference was M A T H ... M O R E M A T H ... then four or more semesters of C A L C U L U S.

In fifty years I've forgotten most of that MATH and Calculus stuff, but I still like to read about the humanities, history, sociology. That must mean something. My degree, like Cecil's, is a BS [That does not stand for Bull S...]

I agree that in the coax side, there is no real 0V because the current has a standing wave. But the transceiver has a DC power supply (normally 12V) that is controlled or modulated. One side of the power supply is regarded as 0V and connected to 0V rail of circuits. The modulated side is the RF live that is connected to the centre contact of transceiver output connector.

In theory, while transceiver is transmitting, if I touched the outer of the output connector, I would not expect to get a shock or RF burn. If I touched the centre contact of output connector, then I would expect to get a shock or RF burn. Admittedly, I could touch the outer and find that I am close enough to the centre contact for RF to capacitively couple into me. In real life, I would never touch the output connector while the rig is transmitting.

Does RF live and ground not exist on the output connector of the transceiver?

>transceiver?

"Live" and "ground" aren't absolute, universal things. These terms exist only in relation to a specific reference point, which you must choose.

Yes, it's true that the outer rim of the coaxial connector is usually tied to the chassis of the transceiver, and that this chassis is also tied to your DC ground. So, the potential voltage between the connector and your body is usually low and it's not all that likely to shock you.

However, this doesn't mean that this same thing is true at the other end of the coaxial cable (i.e. up at the antenna)! Although the far end of the coax braid is at (or very close to) DC ground, it's far enough away in RF terms (that is, in terms of wavelengths) that its voltage is going to be very different much of the time.

Consider also the case in which your transceiver isn't "grounded" at all... it's sitting on a wooden table, powered by a battery, and the coax cable runs directly from it to the antenna. There's no "third wire" in the power cord, or other grounding wire connecting the transceiver to a water pipe or electric outlet or a grounding rod or anything like that. Let's further assume that your antenna is a vertical, with radials, elevated up on an insulated mast.

Now, when you transmit - what's the voltage present at the base of each radial? If it's "0V", then why, and with respect to what?

Hi Dave,

This doesn't really make much sense. Even discounting that and trying
to extrapolate your response, it isn't even 0V then and not true for
SWR in general.

>But the transceiver has a DC power supply (normally 12V) that
>is controlled or modulated.

A modulated power supply? Even if you mean regulated, it bears no
resemblence to the topic.

>One side of the power supply is regarded as 0V
>and connected to 0V rail of circuits. The modulated side is the RF live that
>is connected to the centre contact of transceiver output connector.

It will, then, come as a surprise to you that the output of the
transmitter comes from an AC coupled link. You may choose either wire
in that link to go to any part of a ground system, or conversely, to
what you consider to be the radiator. It makes no difference because
there is no
Ground
Hot
Cold
Dead
Live
or any other distinction until you plant that wire. You can paint
that wire turquoise in the belief that it is safe, and grab it at a
later time to fry you.

>In theory, while transceiver is transmitting, if I touched the outer of the
>output connector, I would not expect to get a shock or RF burn.

Expectations here are a belief system, not a proof. I suggest you
stay away from situations that encourage such lethal presumptions.

>If I touched
>the centre contact of output connector, then I would expect to get a shock
>or RF burn. Admittedly, I could touch the outer and find that I am close

>
>Does RF live and ground not exist on the output connector of the
>transceiver?

There are no absolutes as you might expect. Plenty of correspondents here complain daily of problems stemming from what you might deny. If you worked your rig on 10M or 20M from the second story window, you are so far from ground, electrically, that its apparent proximity is only an illusion.

SWL's should learn CW too.

You never know when you might stumple across a station in distress sending
an SOS and you might be the only one that hears it and can get help.

But it seems all SWL's want to do is sit around like blobs all day long
and tell themselves their cheap plastic Etons and Grundigs sound good.
They don't want radio skills if it takes a little work to learn them.

I'm guessing that's why Telamon hates CW and ham radio as well. Laziness.

Miguel
There are "eyewitness accounts" of all sorts of foolishness.

If you build it perfectly a bazooka will show a decrease in SWR over a very small range either side of resonance (SWR = 1:1) when compared to a dipole. This is completely useless except as an academic exercise.

Here's how it works:
The antenna is a parallel-resonant network (the bazooka) in parallel with a series-resonant network(the dipole).
The parallel resonant (tank circuit) network stores energy and will oscillate at it's DRIVEN frequency when driven near resonance, so it stores the energy that would otherwise be reflected as long as it oscillates. Go too far from resonance and it quits oscillating. This effect manifests itself at SWR of 1.2:1 or lower. It flattens the SWR curve very near resonance.
The 2:1 bandwidth is unaffected except by the additional loss of the tank circuit sitting across the dipole feed point.

What Walter Maxwell showed explicitly is that any increase in SWR bandwidth is entirely due to loss, if I recall correctly.

So all the trouble of building a bazooka with both legs and the dipole resonant at exactly the same frequency is a waste of time.
A simple dipole works a bit better and is *MUCH LESS* work and expen$e.

The Double Bazooka is probably quieter than a plain dipole
because, unlike a plain dipole, there is a DC path between
all points in the antenna thus minimizing the effects of
precipitation static.

So a nice 2.5 K ohm resistor at the feed point of a dipole would be vastly
less work.

"With
>> the bazooka we listen stations that we don't with the plain dipole"

I doubt anyone can document that.

You need at least an odd number of 1/4 wavelengths to satisfy the boundary conditions.
You need at least three to define a plane (or cone, if you want a 50 ohm feedpoint)

Bart -

Skip it an move on (DON'T BUY IT).
The radial field is 1/2 of the antenna - for a 1/4 wave vertical !!
IF $$ your problem, save your $$$ for the right antenna -- in your
situation.

You would be better served purchasing a 1/2 wave vertical ---
that does not require the radials field !!

==========
You've been reading books and magazines about rules-of-thumb written
by old-wives. At 3.62 MHz and a radial length of 16 metres the
attenuation approaches 100 decibels. So there's no current flowing in
the radials beyond 5 metres. You can remove the excess 12 metres.
They are not doing anything. What small current density there is
beyond 5 metres is all flowing in the soil. The cross-sectional area
of the soil carries the small current just as well as the radials.
==========

==========
Yes. Use the program to calculate efficiency with the extra 20
radials. Assume all the radials are 5 metres long. But you may not
think the meagre 3% or 0.13dB in efficiency is worth all the labour
and back-ache. By now you are beginning to appreciate how useful the
program is.
==========

==========

Hasan, if I were you I would lay some extra short radials between the
existing long radials - and get some Sloan's liniment to be massaged
into my back. But the increase in efficiency would be un-measurable.
You are fortunate to have very low soil resistivity. Mine is about 70
ohm-metres and for years on the 160m band I have had 7 radials about 3
metres long plus an incoming lead water pipe.

Reg,

NEC4 engine can accommodate on the ground or buried radials in modeling and calculating vertical antenna parameters and performance.

I bet Roy has his hair standing up, or perhaps still trying to recover from the "appreciation" of your program, unless he is still running calculations :-)

You are trivilializing, ignoring 100 years or so of vertical antenna research, measurements and misleading innocent users of your program. You might be right in calculating the resonant frequency of piece of wire in the dirt, but that is far from its contribution to the vertical antenna performance and efficiency.
You better switch to some better quality vino and read up on the subject. :-)

Thanks Cecil

I haven't experience with the antenna, a colleague suggest possibilitie in a RC meeting, but fans of bazooka insisted on "all wheather quieter" (in addition, on various internet selling sites bazooka it is offered being "less noisy").

I think if this was the case would be enough to install on plain dipole a RF ckoke or standard trifilar balun + a ckoke to ground on de rig. what do you think about?

I have seen very well documented measurements about claims about "EH Antennas" (my predilect Roswell alien antenna :>)), but i haven't find anything similar about "silents bazookas" :>(

Here, there are many "hard to die" myths, and I can´'t deal alone with all of them, hi hi. SWR related are the mains but antenna gain specific myths run "elbow to elbow"

Yes, it has nothing to do with SWR or bandwidth. I reduced
the precipitation static problem in the Arizona desert by
going to a full wave 40m loop, the one on my web page.

I would like to see the noise comparisons among a Double
Bazooka, a plain dipole, and a folded dipole. My Arizona
desert precipitation problem certainly decreased when
I went from a G5RV to a full-wave 40m loop.

With the G5RV, one element was grounded through the coax
shield and the other element was capacitor isolated from
ground by a series cap in my transceiver. It arced at the
coax connector and a choke did solve the arcing problem.

Here in Buenos Aires (near de Atlantic Ocean and the River Plate) it is a very humid area, our typical old wives phrase for all the illness is "lo que mata es la humedad" (what kills you is the humidity) ;>)

(R to Adam I don't see your 2k5 answer, and R also to your doubts about a documented quieter performance, well, I am just searching for a documented falsehood of these extended claims, hi hi)

Another antenna very reputed here as "quieter" it is a simple triangular loop, similar to Cecil's example, maybe the static explanation is OK.
But... very few days at the year we have low humidity climate. (I never have burn a FET o MOS IC by touch them in my 38 years of continuated activity in electronics, but, yes, I kill various equipments by invert its polarity :>))

Do you think that static precipitation it is a valid explanation in these conditions?

cheers

Miguel

In that case the AM carrier is the BFO for the CW signal.
How many SWL's are going to accidentally "detune it right"
for the purpose of hearing an SOS?

How did you verify your program Reg?

I can go outside right now and measure current in a 40 meter vertical radial system, and 100 feet from the base there is significant radial current.

Your programs results also dramatically disagree with Brown, Lewis, and Epstein's data in one of the most comprehensive radial studies ever done.

No. It makes no difference at all.

If you have a static build-up problem all you need do is install a leak resistance or a suitable RF choke to ground. One should have that in an antenna anyway.

I have the choice of any antenna I want and unlimited space to install them. I often have several antenna types up for any one band at the very same time. I've had a coaxial dipole up along with another dipole the same height, and there is no noticeable difference in any aspect of performance. I've even removed the shorted wire connection (the center conductor connection past the feedpoint) and restored it, and the antenna performance remains virtually identical in both noise and bandwidth.

It certainly made a difference in the Arizona desert under
conditions that cause precipitation static in a dipole with
no DC path between the elements. Many hams have direct
experience and have reported it. Here is a discussion of
such over on eHam.net.

http://www.eham.net/forums/Elmers/83174?ehamsid=87e9956f8473775c84a978db4ce15751

> If you have a static build-up problem all you need do is install a leak

But a lot of hams don't know that and run their dipoles with
the two coax conductors DC isolated from each other. I'll bet
the "plain dipoles" being described by lu6etj as noisy don't
have a leak resistance. The Double Bazooka is automatically
protected from static buildup between the elements as are loops,
and folded dipoles.

You can hear the change in noise as a carrier goes on and off. It's
extremely difficult to copy high speed CW like that if the signal is
strong, but a weak signal or slower CW is just as easy to copy as
noise as it is to copy as a pure tone. T1 doesn't mean uncopyable, it
just means ragged tone.

So now amateurs and SWL's should be Morse code proficient
not only using tones but using the swishing sound made when
a BFO is not present?

My concern would be the port- port isolation of the A/B switch. Depending on
the mfg, they're all over the map.

Do your predictions fit BL&E's measurements, or those of Sevick, for
any assumed values of ground resistivity and permittivity?

Also , please tell us more about the fan of 1.0m radials, on the ground,
that will give ninety-several percent feedpoint efficiency.

Not vouching for "degree of accuracy", but here's how I estimate efficiency:

(Known Rrad/Measured R at X=0) at the feedpoint.

If my Inverted L has a predicted Rrad of 25.9 ohms and I measure the R at resonance as 29 ohms, the 3.1 ohms is return loss. This would indicate an approximate efficiency of 89%.

It seems to me to be a fair approximation. When you have added as many radials as possible and watched the input R at the feedpoint (at resonance) drop asymptotically toward the predicted or "known" Rrad, your final "R" value is used in: Rrad/R. For a perfect ground Rrad = R

I use an MFJ-269 antenna analyzer for the measurements.

Have I gone astray? (aside from my starting value of Rrad, which I took from two sources: your rule of thumb formula for Inverted L's, and ON4UN's Low Band DX'ing Handbook). Both your formula and ON4UN agree as to the value of Rrad for my antenna.

I'll replay to other aspects of your response in another post.

73 and thanks for the new program. As you can tell, I've been playing with it. As you can also tell, the implications with respect to length of radials required for good efficiency are causing my brain to cramp.

Reg,

I think you made a typo...if I go with the shorter 5 metre radials, I have enough wire to put in 66 more radials, not 20. If I stay with my existing 50' length per radial, then I have enough wire for 20 more.

I have the wire. It won't be used for antennas. I have 200 more lawn staples, so there is no burying, they are "stapled" to the surface, soon to fall below the "thatch". My 1000' of copper wire has become too valuable to let sit on spools in the basement. (In case you haven't noticed, copper prices have gone through the roof!)

So...I'll be putting down either (20) x 50 ft or (66) x 15 ft radials. Don't worry about my back. When you have a radial plate and a light hammer, stringing tons of radials is a piece of cake...paying for the copper (in the future) is going to generate pain elsewhere.

Hasan,

I ran a sample model from Cebik's 2nd book, and compared it with results
from Reg's program. The antenna used in the example is a 160 m vertical,
with
four buried radials. The height of the vertical is 40 m, and the radial
lengths
are 40.95526 m. The diameter of the vertical section is 25 mm, and the
radials
2 mm. Ground Er = 20, and conductivity 30.3 mS/m (33 ohm-m). The radials
are buried 0.163821 m (0.001 WL). The test frequency is 1.83 MHz.
NEC 4 shows in input Z of 47.2 + j 14.44 ohms. Max gain 2.11 dBi at
17 degree elevation angle. At the moment I have not figured out how
to obtain the total radiated power from NEC, other than the numerical
integration of the normalized far field data. For a symmetrical pattern
this is fairly trivial using Excel. The model does not include copper
losses,
so this should be added for accuracy. Reg's program computes the
input impedance as 30.35 - j 53.1.

I think I have all the data for your antenna from your previous post. There
may be some difficulty in actually running it in NEC 4 with the parameters
you have provided. The depth of the radials is so small (1mm), in relation
to the wire diameter of 4 mm. Wire junctions must occur at Z = 0,
and the wire diameter must be less than the segment length, which
obviously cannot be met. Also segment length tapering would be
required in order to keep the number of segments at a minimum, and
avoid excessively long run times. In effect your radials are close enough
to be considered laying directly on the surface of the ground. Cebik
does imply this is acceptable in his book, but on his web site
states that NEC 4 becomes unstable with wires in the region of Z = 0.
I assume this also applies to wires below ground. Under certain
conditions wires can approach the ground to within 10^(-6) Lambda
(about 0.1 mm at 3.62 MHz). Based on these constraints I could

develop a model, which will probably be close enough.

73,

Frank

If you can copy CW, you can copy CW. The tone it's coming in with
doesn't make much difference. I've copied signals so weak that they
were just changes in the quality of the noise and I've copied perfect
S9++T9 signals. They were all mostly R9. The R only changes if the
signal fades completely out or if there's interference that masks the
signal. Try that with PSK.

Hey Cecil,
Would you do me a favor, please.
Note this thread has been being crossposted to all of these
newsgroups,

rec.radio.amateur.antenna,
rec.radio.amateur.policy
rec.radio.scanner,
rec.radio.swap
,rec.radio.shortwave

I don't know which one you are reading and posting to it from, but I
assume the antenna newsgroup. I am onlt posting this to the antenna
group.

This topic really only belongs in the policy newsgroup, so would you
please edit your replies and delete out all of the other newsgroups
where this topic is not relevant?

Then the subject will either die out, or it will be propagated over in
a newsgroup where people care about something rather than antennas.
For me, I wish crossposting was not possible..... why do we have
separate newsgroups?

Thanks very much, keep up the great antenna postings,

Rick K2XT

NO, the Cushcraft R7 product will easily fit. Now, IF 75/80 meters is your
BID band that you want to work -- it is a challenge with small space and a
vertical (limited bandwidth between 2:1 SWR points.

The Hustler 5BTV is probably the BEST BUY for 1/4 wave verticals.
http://www.dxengineering.com/ProductDetail.asp?ID=13&SecID=16&DeptID=8

DX Engineering is the best Internet web site for buying Hustler x-BTV series
HV verticals and ANY parts or accessories that you may need.
http://www.dxengineering.com/Sections.asp?ID=16&DeptID=8#Top

STOP, TAKE A BREATH, PULL UP A CHAIR and YOUR FAVORITE BEVERAGE.
Time to read - and learn from the mistakes and lessons of others -- that is
why you posted your question - otherwise if you have spare time on you hands
to repeat previous mistakes and dead-ends that is your decision and
responsibility.

Here are 3 installations of 5-BTV that produce the desired results

Maybe we can get Fear Factor's engineers to calculate the number of
boxes needed to perform the test. One of us will have to drive our
car off a cliff and make signal reports as the car goes down into the
boxes ;)

Not if you are looking at trap designs. IF you deisre ONE band verticel -
DX engineering is now offering a 40 meter (24 feet high) and 80 meter
vertical (41 feet high)
http://www.dxengineering.com/Parts.asp?ID=1277&PLID=213&SecID=113&DeptID=22&PartNo=DXE%2D80VA%2D1

What kind of loss will I have if I install this antenna on our 2nd
story roof, but below the ridge line? We live in a neighborhood where
no one has an antenna and wife is worried about the ascetics of it.

Channel Master 4228 with a rotor of course.

>no one has an antenna and wife is worried about the ascetics of it.

When the antenna is pointing towards transmitter towers for which it has a clear field of view (that is, not towards the house's ridgeline) it ought to work well. The presence of the ridgeline "behind" the antenna ought to have only a minor effect, because the antenna is equipped with a reflector that will make it quite insensitive to signals arriving from behind.

On the other hand, if you rotate it so that it's trying to "see through" the ridge line of the house, to a transmitter tower located on the opposite side of the building, it could perform rather poorly. Just how poorly will depend on the actual construction of the roof. If there's a significant amount of metal involved (if e.g. the inside of the roof is insulated with batts of fiberglass that have a foil vapor barrier) you'd have to expect a lot of signal attenuation, and you might or might not get an acceptable signal. In this situation, you might actually get a more usable signal by rotating the antenna so that it points _away_ from the transmitter, and towards a nearby building or other structure which reflects some of the signal from the transmitter.

The key thing to remember is that UHF signals travel almost entirely by "line of sight", and to a lesser extent by line-of-sight with one or more reflections. You can't count on much of the signal either getting through, or diffracting around solid obstacles between your antenna and the transmitter.

Not exactly. Body of the vehicle behaves more like a ground plane and a capacitor coupling to the ground. As soon as "radials" or ground plane has antenna mounted somewhere else than on the edge, you get cancellation of current along the body - two sides "working against each other". We are talking vertical antenna here, not a goofy dipole.

>>> Seems the truth might lie somewhere in between. If the ground
>>> plane of a vertical antenna is near the ground, there are
>>> losses. If the ground plane of a vertical antenna is located
>>> 1/2WL above ground, the losses are a lot less. I'll bet that

>>

Depends. If vehicle is going over metal grid frame bridge or good ground, like salty beach, the efficiency goes up. Body of vehicle is like a plate of capacitor, coupling the ground plane to effcient ground and performance of the vertical goes up, especially at low angles. Drive over the bridge or ocean beach and see the S-meter go up.

CM,

OK - Lets make "CW" 5 WPM a High School Graduation Requirement
and Start the Nation-Wide Testing of Every Child at Every Grade Level
to Ensure that Our Kids Know "CW" ! ! !

We can call it the Uniform Education "Code" {CW} Law -and-
Require that No Child Is Left Behind the "CW" Learning Curve !

Why should only White Males 'know' CW ? ? ?
Equality Demands that Women and Minorities "Know" CW Too ! ! !
- - - We need an Urgent National Federally Funded Program
to Close the "CW" Gap [.]

oops - am i ranting ? ? ? . . . oh never mind ! ~ RHF

913. Diamond X-300 poor SWR on 2M OK on 70cm

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-20 22:35:34 UTC
From: ferrymanr <richardferryman@btinternet.com>
Message-ID: <UPGdnUvq9rCmmF3ZRVny1g@bt.com>
Source record: 55950

I have an X-300 which used to work well but has been stored away for 3 years. It has now been erected well in the clear and fed with good coax. SWR is good on 70cm and very good gain but SWR is high on 2M, causing power foldback on the TX. Anyone have any idea what could have gone wrong? The internal element loks good and the centre joint OK.
Richard

This ham know CPR.

I wonder how many a retired old-timer who decided to join ham radio
stroked out instead while doing speed runs trying to get to 13/20wpm on
CW?

CW kills.

915. Question for You Grounding Gurus

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-20 23:12:56 UTC
From: Brian Kelly <kelly@dvol.com>
Message-ID: <1153437176.242544.67620@m79g2000cwm.googlegroups.com>
Source record: 55952

I have to transport four U.S. standard 5/8" dia x 8' long ground rods 35 miles in my four door compact car. Do not want to carry them on the roof. If I cut them to six feet long I can load them inside the car. Ignoring any code compliance issues would there be any reason the shortened rods would not work as well as full-length rods for purposes of ligtning protection and the usual HF station RF grounding? Soil here is probably very conductive (damp heavy loam). Thanks.

open the windows and stick them out for the drive. this works best if you
open both the driver and passenger windows on the front doors and put the
rods sideways across the car, this way they won't rub against any upholstery
and you can keep a close eye on them the whole way.'

Many SWL's are Ute listeners. They are the ones most likely to stumble
across an SOS.

Just like a person isn't a real ham unless they've passed a code test, a
shortwave listener isn't a real SWL unless their receiver has a BFO.

(SWL's who listen to shortwave with antique receivers are exempt.)

The negative comments occurred because of errors in
the attribution of your posting. It wasn't your fault
so please don't worry about it.

Back to Double Bazookas: It is a well accepted fact that
insulation reduces the precipitation static problem.
So the Double Bazooka reduces the precipitation static
in two ways. 1. DC path between elements, 2. Insulation.

Stick 'em in the back side window, over the front passenger seat, stab
'em in on the front floor, blunt end down. Maybe you could also lower
the front seat back. A few towels would protect things.

If you are doing this for someone else, or a contractor, I'd talk to
them first. While you could easily make up the difference in ground
effectiveness by simply adding another one or two 6' long rods to the
system with those shortened rods, some codes do require 8' in their
language..... not that anyone is really going to pull them out to check!

Or you can do as Dave suggested in his reply to you and just open your
car windows and stick them crosswise.... should be little sticking out of
either side that way.... especially if they are diagonally across.

Personally, I think one can never have a good enough ground where
lightning is concerned.... but I'd say you probably won't significantly
be lessening your effectiveness with 6' rods vs. 8' rods.

In this part of the world one can buy joiners for the rods. The idea would be you cut them in two, then when you install them, drive the first rod, put the joiner on, place the second rod in the joiner, drive it etc. That's how rods of tens of metres are driven in.

Maybe those joiners are available from you electrical contractors suppliers.

I should have explained that that's what I want to avoid. I boogered
it. Sorry Dave.

I took the out-the-window approach a couple years ago and got whacked
by somebody in a van who came very close to side-swiping me. Shoved the
rod back into my upholstery and dinged it and I almost lost my
passenger-side mirror. I guess I'll have to bite the bullet and car-top
the full-length versions Tnx.

Brian,

I know this doesn't answer the transport problem, but what are you
going to do with the rods?

Lightning protection comes much more from how you wire things than a
few ground rods...or even a dozen ground rods. As a matter of fact
adding or improving a ground can make things worse if the bonding and
entrance is installed wrong.

The station ground always should attach at the cable entrance point,
and that entrance MUST be bonded to the utilitly entrance ground. Many
people don't do this even though it is critical.

I have virtually no ground rods at all at my shack entrance, I leave
all the cables connected all of the time, I have several tall towers
including one 300 ft tall that gets hit several times a year, I have
virtually no in house lightning arrestors on cables, and I never have
lightning damage inside the house. I do have a cable entrance panel for
all cables, and that panel is bonded to the power mains ground and
telco ground.

The reason I don't have problems, even though the magnetic field from
some hits is so strong it magnetizes the TV screens, is how things
enter and how they are "grounded" to a common point. I haven't even
lost a computer modem.

As for RF, unless you are end feeding an antenna the only way
RF-in-the-shack is an issue is if something is wrong with an antenna
system...either in basic design or layout. Any two conductor feeder,
either balanced or unbalanced, should not produce RF in the shack.

I A B tested a regular low dipole made from number 8 AWG bare wire against a double bazooka. Even during severe weather there never was a difference in measureable noise levels.

That's just from a direct observation over a long period of time between the two antenna types.

There also was no measurable or noticeable difference in signal strength or bandwidth.

Brian, these ferrules are for copper clad steel electrodes. The are slimline, and have a hole with a slow taper bored in each end. They are "connected" during the driving process, no silver soldering etc. They cost about six pacific pesos for half inch rods, equivalent to about $4+ of your money.

Did you A B test them under precipitation static conditions?
If not, the test was incomplete. There is obviously a charged
particle difference between a bare wire dipole and a double
bazooka. If you weren't testing using charged particles, the
test was just as obviously incomplete.

Hi Hasan,

Roy Lewallen and I just measured some ground systems. Actual measurements using good instruments, not guesses or models.

In one case we had an antenna with four elevated radials that within measurement error (using lab type gear) had equal signal strength level as the very same vertical element over 16 buried radials. As I recall the buried radials had over 60 ohms of base impedance, the six foot high elevated radials was down around 40 ohms or less.

Over the years I have measured many antenna with very low base impedance and terrible efficiency, I have measured verticals where changing the ground system did not change impedance but improved field strength, and it is very easy to find cases where changes in a ground system can have MORE efficiency with higher feed impedance without changing anything but the ground system.

Over simplification of a complex system will often not produce reliable results. Just look at the results of Reg's progam where it predicts highest efficiency with very short radials. We all know that doesn't happen, but the oversimplified program says it does.

Thanks for the reply, I suppose you figured out I was playing on
Cecil's reply.

Tonight, I did have a related experience. I have an FM BC band xmtr
in the car attached to my CD player. I use it to monitor the cds on
the car stereo. I noticed tonight when I crossed a very high bridge
that Radio signals drown out my little monitor transmitter, only while
I was on the bridge. The car was specifically over 1/2 wave above the
highway below it.

for what it's worth....
:)

938. Aluminum tubing for vertical antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-21 06:24:23 UTC
From: Hank Zoeller <bogusaddress@dontbothernotvalid.com>
Message-ID: <44c07393$0$10058$c3e8da3@news.astraweb.com>
Source record: 55975

Hello everyone,

I'm contemplating putting up a vertical antenna for HF use. I'm looking at an approximate height of 30 feet or so. I am thinking of using aluminum tubing (0.058" wall) in a 'telescoping' manner. Here are my questions (so far):

1) Diameter. For wind resistance, should I start with something like 1 inch diameter and work down to 3/8 inch? Would the antenna be stronger if I started with 2 inch diameter and worked down to 1-3/8 inch?

It would seem to me that the larger diameter might be better able to withstand wind but it would also offer more resistance to wind possibly negating the additional strength. But, I have no experience to draw from. So, fat or slim?

2) I am planning a set of guy ropes at about the 12 foot level, a bit over 1/3 height. Is there a better height for guy ropes? I can put as much concrete in the ground as I like, and a very robust mount system is possible. Is there any way to make an unguyed 30 footer that isn't a tower form factor? Something like making the bottom 12 feet or so from 2 inch diameter, 1/4 inch wall tubing and then light weight tubing from there up to full height?

The rods I have seen aren't solid copper, but copper plated over some
other metal. One I saw appeared to have a concrete filling. You may
find putting the rod back together again a little difficult. If it is
just copper tubing, you may find using couplings will put you back in
business..

The brochure for our European subcompact hatchback showed a photograph
with a surf-board inside. They folded down half the rear seat, reclined
the front seat back until it was flat, and then pushed the pointy end of
the board all the way into the glovebox.

It was all highly contrived, and of course "your car may vary", but
maybe some of those ideas will help.

What's wrong with putting them on the roof? They are only 8' long, so they won't overhang. Even without a roof rack it would be a simple matter to protect the roof and tie the rods down.

Ian, you must have had no experience of a few short radials.

Try 16 or 32 radials, 1 or 2 metres long, in good soil, with a 1/4 or
3/8-wave vertical or inverted-L antenna. Radiating and receiving
efficiency will surprise you. Also at all higher frequencies.

At your new QTH you may not find much good soil. But try it anyway.
Or persuade someone else to try it.

I managed for many years with 7 radials 2 metres long, covering an
angle of only 90 degrees. Soil resistivity was only 70 ohm-metres.
Unfortunately, had to abandon it when the garden was turned into a
patio. Damned concrete!

When I bought my aluminum tubing from Texas Towers, they had
a computer program that calculated and specified all of the above.

I understand exactly what you're saying, I agree with all of it and ideally I'd do exactly as you've done. Problem is that I'm not able at this point in history and for several reasons to do as rigorous a a job of grounding as I'd like to. This place is a nice old relic in a mini-forest which was built and wired long before there were any such things as electrical and building codes. I can't tell if the power service entrance is grounded or not but I suspect that if it is grounded it's via the water supply line which is 3/4" copper tubing. Eventually I'll get an electrician in here to sort it out. In the meantime I'm getting back on the air with some simple wires at low heights.

This will not be the fabled W8JI antenna and grounding farm. The antennas will be end-fed 20 & 15M Dale Parfitt half wave dipoles strung up vertically in trees. There will be a ground rod at the base of both verticals to which the coax sheild is bonded. There will be a ground rod at the copper plate cable entrance and all ground rods will be connected via a solid #8 AWG copper wire snaked along the ground. Both verticals will be only 25 feet or so from the station so I expect a lot of RF to be floating around. Which will need grounding.

I have homeowner's insurance, I'll buy some ARRL equipment insurance, I have two 10 pound dry chemical fire extinguishers and I go to church. Once in awhile . .

Back to finding a pair of cartop cargo carriers which work with these new-fangled aircraft-style flush doors . .

<<grumble>>

Thanks Tom.

That sounds like scientific validation of a program or theory, compared to all the work Brown, Lewis, and Epstein did with field strength meters.

Maybe that's where S units came from?
S-urprise units?

I managed with a ground rod. I managed 12 dB better with radials.

Who was it that said if you can put a number on it you don't understand it? Someone in England I think.

Source record: 55887

The windload on a piece of tubing of a given height is proportional to the radius, but the stiffness of a piece of tubing is proportional to the fourth power of radius.

So, as you make the tubing bigger, the stiffness goes up much much faster than the windload, so bigger tubing will always be stronger unless you make the wall very, very thin compared to that of the smaller tubing.

Now, the weight of the piece goes up too, and the price is proportional to the weight, so you don't see a lot of antennas made of 5 inch aluminum tubing when they don't need to be.

For a freestanding vertical, you're going to get the best results with a taper. It's good for the tubing to get thinner as you go up, because the big problem with a freestanding pole is that the wind is trying to tip it over. The mount at the base has to be strong enough to take this torque. The wind has more leverage when it's acting on the tip of the vertical than when it's acting further down, so having the vertical thin at the top helps reduce the load on the base.

Cecil's suggestion about the Texas Towers calculator is a good one. Also, after you put up a vertical you'll have more intuition about this. I wouldn't make it a 1 inch vertical all the way up :-).

I had a 40m vertical, 4 elevated radials at 15 feet and 1 inch tubing from that point up to about 25 feet, with smaller tapered tubing and rod above that. It worked OK, but had to be guyed in two places! It also snapped in half in a windstorm. Bad mechanical design, but I made do because I had the tubing. It would have been a much nicer antenna if I'd purchased the proper materials.

Sorry, that should have been that my vertical had 25 feet of 1 inch
tubing topped with smaller stuff... so 1 inch tubing from the 15 foot
level to the 40 foot level with respect to the ground.

The feedpoint was at the top of 15 feet of radio shack TV mast.

Flimsy bugger, anyway... pretty good antenna though!

You're right. I gotta go looking for a general-purpose rack. Which
would greatly simplify hauling lumber and 12' lengths of aluminum
tubing too.

Hi Tom,

I understand there are measurement issues (and certainly assumption issues for Rrad). Isn't is fairly certain that increasing the number of radials (of proper length) until the feedpoint R (at resonance, at the antenna) no longer drops, is a reasonable approximation of "high efficiency"? The only issue I see, is determining the target Rrad to compare it to when trying to "estimate" efficiency.

Are you saying (for example), that the feedpoint R of a 1/4 w vertical against perfect ground cannot be reliably estimated at 37 ohms? If it can, then isn't 37/R a measure of efficiency?

Again, I'm thinking of the efficiency of the ground system... I have no way to look at field strength.

Is it really possible to reduce ground losses to the absolute minimum and not have a corresponding increase in field strength?

This is starting to turn into "black magic" for me. I can understand questioning a particular "number" for efficiency based on the simplistic Rrad/R formula. If the implications go further...indicating there is no meaning to Rrad/R, then I'm lost.

Perhaps the issue is that it's known how to maximize efficiency, it's just completely unknown what that efficiency really is, and there is no simple way to measure it. If that's what your saying, then I understand.

That position does seem to muddy up the "how many radials and of what length" efficiency info presented in ON4UN's book and referenced in other texts. They all seem to acccept some sort of accuracy for the Rrad/R formula with 1/4 w verticals. If I understand you correctly, the formula is rejected outright as hopelessly simplistic, and of no particular value.

Do I have it now? If so, I'll refrain from using it in the future.

Thanks for the comments.

NEC 4 can be easily used in a few hours with some reading. To
really understand the program would probably require
the equivalent a 3rd year university semester. The program can,
however model an infinite number of antenna designs.

Inputting data is relatively trivial. NEC 4.1 is free, but does require
the purchase of a license from the Lawrence Livermore
National Laboratory. The cost of a license for non-commercial
use is $500.00, and is available to those living outside the USA.
For US residents the license is $300.

For much easier data entry, and error checking etc., GNEC, from
Nittany Scientific makes life a lot simpler -- cost $795.

I had always assumed that a NEC model of a perfectly conducting
monopole above a perfect ground would provide the radiation
resistance. For example, considering your antenna of 18.3 m
at 3.62 MHz, the input impedance is 27.5 - j 64.7. The radiation
resistance would therefore be 27.5 ohms. This appears to be
fairly close to your estimate of 25.4 ohms.

If the field strength coordinates were the same for
a perfect antenna model and a real-world antenna
model, would the ratio of the areas under the curves
yield the simulated efficiency of the real-world model?

> > ==========

To Hassan et al,

In all my programs, where antennas are involved, accuracy of results is usually better than than that needed for the purpose of the program.

In the case of RADIAL_3 the obvious purpose of the program is to assist with choosing an economic length and number of radials to be used with a given test antenna height. It is also educational in that after reading the introductory notes and using it, the user will have a better understanding of how radials work.

To summarise, the program tells the user the maximum economic radial length occurs when the attenuation along it is about 18 to 20dB at the lowest frequency of use. But where his back yard is not big enough, even shorter lengths can be quite satisfactory. At HF, where small standing waves may occur with normal soils, radial lengths can sometimes be judiciously adjusted to minimise loss.

To increase efficiency when the 20dB limit has been reached it is necessary to increase the number of radials. And that is subject to rapidly diminishing returns. As is easily and adequately demonstrated by the program.

Prediction accuracy can be no better than that of the input data. And nobody knows what the soil resistivity is in the near field, ie., under the antenna, to better than + or - 40 or 50 percent. That's why NEC4 and the like (or B,L&E) can be no better at predicting results than RADIAL_3. NEC4 may be highly accurate at predicting radiation patterns in a hoped-for ideal environment but that is NOT the purpose of RADIAL_3 which is essentially practical.

If I published the source code hardly anybody would be capable of making any sense out of it. Some of you old-wives, who imagine you know more about modelling and programming than I do, would attempt to ridicule it, thus degrading its usefulness to the ordinary amateur user. Mud-throwing always sticks.

In the meantime, WW3 is escalating with even greater rapidity!

Hi Frank,

I think the general question became "can one use this Rrad value in calculating efficiency". I'm waiting for Tom's response to my last posting.

On the other issue, radial length vs. usefulness, (I tried a diect mail to you and it didn't make it cuz I forgot to take out the nospam part),

here is what I want to know from NEC-4:

Radial wire is #14 THHN inslulated wire. I approximated it at 2mm. The antenna wire is 4 mm. For these purposes, you can probably forget that the wire is insulated.

Now...looking at radial length (assuming 26 radials), and given the constants I previously provided, how long does a radial in this configuration have to be, before it is no longer valuable to increase its length. Tom says he measured significant current in a radial well beyond where Reg's program says the current had diminished to insignifcant levels.

I would be MOST interested if you can confirm Tom's measurements. If NEC-4 says there is substantial radial current where Reg's program says there isn't, then that is an important contradiction, putting Reg's model into question. I'm giving more credibility to NEC-4 (properly used) than I am to Reg's own design. If, however, we have two sources (one measurement based: Tom, one model based: NEC-4), that say Reg's theory that radials quickly approach maximum effectiveness over a MUCH shorter run than has been previously understood (in moderate to very good soils), that contradict Reg's algorithim.

Having only looked at conclusions from BL&E, I can't say what their measurements indicated in terms of radial current vs. length. Ian has suggested that they did measure the radial current vs length and they concur with Tom. So, if BL&E and Tom (both empirical), as well as NEC-4 (model based), all say that important levels of current are present in radials well beyond where Reg's program predicts, then there's only one conclusion left. (Unless I'm missing something).

This, to me, is much more interesting stuff than a month long peeing contest over precipitation static.(which may be rearing its ugly head yet again in the "double bazooka" thread. God help us!

73, and thanks for your comments and efforts to help me understand what is going on.

>

I understand that Reg, but somewhere in all this an important consideration
is being lost. The issue isn't +/- some questionable percentage of accuracy,
it is the underlying assumption in the model you are using to arrive at the
"much shorter than everyone else's radial length". You have to admit,
predicting 90% efficiency with 5 metre long radials (26 in my example) is
stunning...given BL&E, Tom's measurements, and the yet to be run NEC-4
analysis. We aren't talking small differences here, we are talking NIGHT and
DAY in terms of length.

It really is this simple: Your program predicts neglible current at
distances greater than 5 metres in the example being discussed. Your program
says that any further lengthing is borderline useless. Tom's measurements
completely disagree. BL&E, I am told (I haven't read that section) also
completely disagree. I'm waiting to see what NEC-4 says.

They key is this: are their ANY soil conditions wherein your model of 5
metre long radials (26 of them) will agree with the existing experimental
data, or NEC-4 modeled data? If not, then the "radial as transmission line"
model fails, and should not be used. If one doesn't get the 20 to 25 dB of
attenuation within the radial length limits your program predicts, then the
program is in error and will lead to false conclusions...not just
"inaccuracies", outright major errors. I would love to put in 66 radials 5
metres long and know that they work every bit as well as 66 radials 18
metres long. It would save a lot of money in copper and extra lawn staples.
If, on the other hand, your model is wrong, then a lot of work has been done
for next to nothing. If the purpose of the program is to help in this
process, the program must be trustworthy in its MAJOR assertions.

==========
We need to know: does the predicted attenuation of current along a radial
wire happen as quickly as you predict? This can be measured. This can be
modeled. That's what makes this fun. Let's find out. Let's see what agrees
with what and what doesn't. Then we can conjecture as to why, and which
approach is to be "believed".
==========

I'm not denigrating your work. I have all your programs and play with many. I have found several to be wonderfully useful. However, when something is called into question, I'm just not religious in scientific matters. Even the Qur'an says, "Bring your proof, if ye are truthful." (sorry, I couldn't resist)

Cecil,

There is absolutely no reason to believe that one antenna is less
responsive to charged particle noise than the other. Whether or not
the antenna can accumulate a static charge is a separate issue.

Hasan et al,

Tom says current can be detected in radials well beyond the 20dB attenuation limit. This is easily explained.

The total current flowing in the system at a distance is in the soil due to its far greater cross-sectional area. Especially when soil resistivity is low. Nothing in particular happens in the soil at the end of the 20dB limit.

The small current in a radial is INDUCED in it by the relatively larger total current flowing in the soil in parallel with it. The radial current is NOT generated by the voltage at its input. Its high attenuation isolates it from its input.

What current flows in a radial has a progressively less effect on the total current (which is what matters) as distance increases. Eventually, it doesn't matter whether the radial is there or not.

The limit is reached when the radial input impedance converges on Zo, the radial's characteristic impedance. This occurs when radial attenuation is around 18 or 20dB. Beyond that distance the current flowing in the ground carries on, as usual, unaffected whether the radial is there or not.

Resonant effects, small peaks and troughs in the impedance-frequency curve, also die away at the 20dB or even lower limit. There's not much left even at 14dB.

Radial attenuation increases rapidly with frequency. So shorter radials can be used at 14 MHz than at 1.9 MHz. When 30 MHz is the lowest frequency of use, and soil resistivity is high, a dipole, without radials, is more likely to be used than a vertical.

(Comment: I guessed correctly I would be accused of trolling when I introduced the subject of radials as transmission lines.)

If the antenna is mounted just level with the obstructing ridge, then
the refraction over the ridge is only about 6 dB less than when the
antenna is in the clear.

But below that level the refraction loss increases very rapidly.

What about all the web references that say precipitation
static can be decreased by insulating the antenna from
the charged particles in the air?

Think about it. A charged particle hitting a bare wire
will likely transfer a charge. A charged particle hitting
an insulated wire may or may not transfer a charge depending
upon the insulation.

After all, air is an insulator. A charged particle missing
the antenna entirely is in contact with that air insulator.

I once had a ladder line fed doublet.
It was disconnected at the feedthroughs because a thunderstorm was about ten
miles North.
I could pull 1 inch arcs off the feedthroughs to a grounded wire.
Made me think of Ben Franklin.

975. Length & number of radials again

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-21 19:44:15 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <1bOdnTnoDO8PslzZRVnyuA@bt.com>
Source record: 55912

Radials Continued.

Perhaps some kind person who has been able to afford the latest issue of NEC4 could calculate the radiating efficiency of a typical vertical antenna of height 9 metres (29.5 feet) and diameter 50mm (2 inches) -

- when fed against a ground system of 50 uniformly distributed radial wires, each 1.64mm in diameter (14 AWG) buried to a depth of 25mm (1 inch), of length 10 metres -

- in soil of typical resistivity = 150 ohm-metres and permittivity = 16.

But first I should like to ask, can NEC4 complete such a calculation without human intervention or assistance? If yes then please continue, perhaps keeping a record of the time involved.

Using program RADIAL_3 the answer is - Radiating Efficiency = 86.0 percent.

If several of you participate, perhaps using different tools, it would be interesting to compare results. By all means, join in!

Thank you for your assistance.

Reg, G4FGQ.

How are you planning on mounting the alum. tubing at ground level?
And what, if any, means are you considering to provide for tipping it
over?
I wonder if it is practical to install say, 4X4 posts in the ground
about 5 inches apart, with another 4X4 as the vertical support for
the aluminum pole. The aluminum pole bolted to the 8 foot long 4X4 at
about the 6 foot level. Would the wood detune the antenna?

No. I'm not saying that.

If it can,
> then isn't 37/R a measure of efficiency?

No. A ground can have transmission line effects. As such, it can modify
impedances.

> Is it really possible to reduce ground losses to the absolute minimum and
> not have a corresponding increase in field strength?

You are assuming a reduction of ground loss or an increase of ground
loss always indicates a certain resistance change at the feedpoint.
That assumption is not correct Hans.

For example, I can measure feed resistance of a mobile antenna on my
truck. By moving the antenna around I can vary the "apparent" ground
resistance from a few ohms to perhaps 30 ohms with very little change
in ground loss.

All I'm saying is the feedpoint reistance change when using a 1/4 wl
series fed radiator does not correspond to change in field strength. I
know that to be absolutely true, because I and others have seen that
happen.

Reg,

I certainly don't think you are trolling. You have aroused a very interesting discussion. I'm absolutely fascinated. The issue isn't whether Tom can detect the current at a point beyond your description. The point is will that current be quite a bit larger than the 20 dB down your approach predicts.

This is getting pretty simple...either the current is or isn't substantial beyond the wire lengths you describe. If it isn't, you have hit on something big. If it is, then the model you are using or the application of that model is in error. I'm just trying to learn which of these two cases is true. I find your analysis breathtakingly interesting. It's just hard to resolve the apparent contradictions....fun nevertheless! Thanks again.

I've been reading this thread, and sent the following msg to hasan. I then decided to post it here for others to see.

Walt, W2DU

Hi Hasan,

I've been reading the radials thread on the rraa, with the works of BLE bandied about. I have a copy of BLE in PDF that I can put on a CD and mail it to you if you don't have a copy, which I'd be pleased to do.

Incidentally, I worked for many years with Jess Epstein, the 'E' of BLE, in Brown's antenna laboratory at the RCA Labs in Princeton, where Brown is the 'B' in BLE. I also know Bob Lewis, the 'L' in BLE, as we've spent many hours together as hams. Bob is W2EBS.

Bob and I were attending a ham meeting in NJ in the 1960s where Jerry Sevick was demonstating how radials worked with verticals. He had annular rings of wire connecting all the radials at various radial distances from the center. He even had a wire connecting the ends of all the radials together. I asked him what the annular rings were for, and he replied that they kept the currents in each radial equal. I asked him if he was acquainted with the BLE paper, and he said he had heard of it but was not familiar with it. So I asked him if he'd like one

of it's co-authors to explain it He agreed, but was totally shocked to know that Bob Lewis was in his audience. Bob then proceded to straighten Sevick out on how radials worked. A fun night, indeed.

The graphs reporting BLE's measurements are pretty conclusive. In addition, the BLE paper is the basis on which the FCC set the requirements for the ground systems on all AM BC stations since 1939. So there's thousands of empirical proofs of the correctness of their measurements in every situation where field strengh measurements were required for proof of performance.As I'm sure you already know, for every AM BC station that uses a directional antenna system the FCC requires field strength measurements. There has never been any such measurements that disagreed with those of BLE. Even Tom's (W8JI)

Please let me know if you'd like me to burn you a copy of BLE.

Walt,W2DU

PS--If any others reading this would like a copy of BLE let me know and I'll burn it for you.

Bummer again! The field strength does change, but you are saying the
feedpoint Z may not track it.
>
> All I'm saying is the feedpoint reistance change when using a 1/4 wl
> series fed radiator does not correspond to change in field strength. I

Then we are left with no use for monitoring feedpoint resistance (other than
matching). Bummer.
All we can do is keep adding radials and watch the R drop until it gets
boring. (Or is that not possible now, either?). Every vertical antenna (1/4
w), I've ever made and played the radial game with has behaved predictably
with increasing numbers of radials...the feedpoint Z has always dropped
asymptotically towards the Rrad of the vertical. Now I have to discard all
that...or are you quoting the exception that doesn't invalidate the general
nature of things? I'm getting that "too many variables to deal with" black
magic feeling again. Things looked so reasonable for a while there...now it
appears for all but the brave, it becomes nothing more than cramming a lot
of wire into or onto the ground and hoping for the best.

Not what I was hoping for at all. Bummer.

Thanks for taking the time to explain parts of this, Tom. (even though it
wasn't what I wanted to hear)

==========

Walt, where've you been lately?

I have no doubt that BLE measurements are good and valid at LF and below. But to extrapolate conclusions up to HF, where amateurs reside, and where funny things happen to radials, is somewhat dangerous.

I understand BLE forgot to measure ground resistivity and permittivity of the site. Perhaps because they thought it didn't matter very much. But such things certainly matter above about 3.5 MHz. At HF radials behave very differently from behaviour at LF if only because the ground 'constants' have changed from their DC and LF values (which are the values usually inserted in HF computer programs.)

Reg.

> ----
> Reg, G4FGQ.

Reg, I made some changes to the antenna, but should not effect
the result too much. The maximum number of junctions without
a workaround is 36, so I reduced the number of radials to 36.
Ok, I know that give 37 junctions, but doubt it will effect the
result. I changed the vertical diameter to #14, since I
had a warning with the 25 mm diameter. Again there are
workarounds, but I did not want to spend all day figuring
out segmentation and length tapering.

You did not specify the frequency, but assume from the
dimensions it is 7 MHz. I used 7.000 MHz. The input impedance is
27.33 - j 109 ohms. Since I am only learning how to use the program
I don't know if NEC can provide the total radiated power. I
computed the total radiated power by summing power density over a
hemispherical region. For 100 W input I get a total radiated power
of 30.5 W. It took me 90 minutes.

Regards,

Frank

All,

Not to minimize the fine offer of Mr. Maxwell, any of you who might prefer to download a PDF of this BL&E "benchmark" paper with empirical data on buried radial ground systems vs radiation system efficiency can do so from the link following the text below, which I posted last December to some broadcast-oriented websites.

N. B. for/to REG EDWARDS (G4FQP): I hope that you will be motivated to follow through on one or the other of these offers, and that you will post a comparison of the results of your ready-to-run, "radial_3" DOS program as compared to the BL&E datum, for equivalent conditions.

RF

Link: Brown, Lewis & Epstein Paper on MW Ground Systems
Richard Fry (rfry at adams.net)
Fri Dec 9 14:54:23 CST 2005

After some "back and forth," IEEE just gave me permission to post the benchmark 1937 paper by Brown, Lewis and Epstein about MW ground systems.

Quite a few on RT and BC asked me earlier for this, but I had to hold off until it was possible. Now I hope all those who asked will see this posting, eventually, and view/download it from the link below. There are some restrictions on its use, as shown in the PDF.

The file size is about 3.3 megs, so a fast connection will help.

Consider the nature of dielectric materials. I could be wrong, but I
bet if you stuck a negative oxygen ion on the outside of a jacketed
conductor, you could make the conductor inside think you had put an
electron directly on it.

>>> After all, air is an insulator. A charged particle missing
>>> the antenna entirely is in contact with that air insulator.

And air, which is an insulator, is also in contact with a bare wire
antenna - presumably 'insulating' it. The difference is one of
density (and dielectric constant).

I suppose if you set up a big electric or magnetic field in the proper
orientation, you could make a lot of the ions go away from an antenna.
But controlling plasmas is kinda like herding cats.

Hi Hasan,

I have not forgotten your model. I am very interested in verifying
the findings of Reg's program, so will get around to it. I will be
very busy this weekend, so may not have a chance until the
beginning of next week. I have been investigating some of
the limitations of NEC, and 1 mm below ground is one of
them (Not necessarily because of the depth, but segmentation
issues). I will try and get as close to your model parameters
as possible. This afternoon I was sidetracked by a challenge
from Reg, and spent about 90 minutes running a model
similar to yours. Interestingly enough there appears to be
a very large discrepancy between the programs.
NEC 4.1 indicated only 30.5 % efficiency.
(See later thread).

For sure, a gradient is established by thunderstorms
resulting in all sorts of electrical and magnetic
phenomena. But the particular type of noise I am
talking about is precipitation static caused by
charged particles hitting a bare wire dipole when
one element of the dipole is floating. In particular,
this type of noise can occur in the Arizona desert
when there is not a cloud in the sky. Here is how
"precipitation static" is defined:

http://www.atis.org/tg2k/_precipitation_static.html

I have mine with the bottom mounted at 20 ft using 2x4s.
The tubing is isolated from the 2x4s by a sleeve of PVC
pipe. There is no noticeable detuning by the wood support.

> electron directly on it.

The question is whether the electron stays on the insulation
or migrates through it to the conductor.

The size of the charge Vs the dielectric determines how
much of the charge actually reaches the conductor. When
I went from bare wire to 600v insulation, my precipitation
static problems decreased considerably. Then when I went to
1000v insulation and a full wave loop, most of my precipitation
static problems disappeared.

The worst case of precipitation static seems to be for
airplane antennas. Insulation is the recommended cure
although folding is also mentioned. Please do a web
search for "precipitation static" and see for yourself.

Cool! Does it calculate the size to use based on expected wind speed?

I looked around on their web site and didn't find a calculator so it must be something they do with you on the phone? I'll call 'em Monday and see what they have to say.

Thanks for the tip!

Thanks, Dan, this is really useful info -- just what I was looking for.

What do you think of having the bottom 12 feet be 2" diameter by 0.25"
thick tubing? If I went up another say 16 feet with 0.059 thick tubing
properly telescoped do you think I'll need guy ropes?

I've been thinking of overlapping the thin tubing in such a way that
there would always be two layers of it for the entire length of the
antenna. It would seem to me it would be much stronger without
increasing the wind loading at all.

Thank you for your insights.

I haven't yet decided how I'm going to mount this thing. Now, I'm leaning toward (pun intended) a larger size of tubing than I initially thought. Once I make a final determination on the tubing size then I'll turn my attention to the mount.

Fortunately, I have a machine shop so I ought to be able to fabricate something worthy.

As to the detuning, I'm not concerned at all about resonance as I'll have a 1-kw antenna coupler mounted at the base of the vertical. I would be concerned about other effects so I'll likely make the mount with as small an electrical footprint as possible.

The fold-over idea is good. I think I'll probably make two of these things, one about 30 feet high and another about 16 feet high for the upper HF bands. It would be cool to be able to switch them out easily..

For about 20 - 25 years I've had four verticals of about 33 foot height in my back yard. They're free standing, no guys. They went through one wind storm with gusts in the 80 mph range, and all other weather, without damage. Each is made of three pieces of telescoping 6061-T6 tubing, 1-1/4, 1-1/8, and 1 inch diameter. The support is an 8 foot chain link fence line pole (about 1-1/2 inch diameter, steel), driven 4 feet into the clay ground. The antenna element is clamped to it with muffler clamps, insulated with a couple of slices of thick wall plastic conduit about 1/4 inch thick.

Ground planes above ground can approximate the results
from buried radials. The wires should be several wire diameters
above the ground, and not < 10^(-6) wavelengths -- providing
that a finite ground, Sommerfeld/Norton method, is used.
The reflection coefficient approximation will produce large errors.

Frank

1001. Re: Length & number of radials again

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-22 06:39:41 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <2_OdnX7zdY6gVFzZRVny3w@bt.com>
Source record: 55838

Frank,

Just to confirm we are both working on the same system, I have -

Number of radials = 36
Length of radials = 10 m
Diameter of radials = 2 mm
Frequency = 7 MHz
Antenna height = 9 m
Antenna diameter = 1.64 mm = 14 AWG
Ground resistivity = 150 ohm-metres
Ground permittivity = 16

IMPORTANT:

If NEC4 gives you the input impedance of the radial system I should be very pleased to know what it is.

Otherwise we shall have no idea where the discrepancy arises - in the radial system or in the antenna efficiency calculation.

Radiating efficiency is estimated by my program by the well-known formula -

Efficiency = Rrad / (Rrad + Rradials)

provided antenna and radials reactance are tuned out.

Whereas NEC4 calculates efficiency by integrating power flow over a hemisphere WITHOUT tuning out antenna and radials reactance.
Altogether different.

Reg, G4FGQ

Problem solved!
After removing the grub screw in the base I extracted the complete element. Checked capacitors and soldered joints - all OK. Cleaned mild tarnish off all element sections and matching sections. Took apart joints where grub screws are fitted and cleaned mating surfaces. All the grub screws were tight so had not worked loose. Also cleaned mating surface between feed and aradial/mount boss. Reassembled and re-erected. Now working fine.
Seems probable that there can be come minor corrosion in joints with grub screws and og the element itself. A good clean up every two or three years would be a good move to prevent losses creeping in.

As I remember, you give them the wind speed and they give you
back the specifications. They ran the program for me while I
was standing there in the lobby wondering what size to buy.
I requested a self-supporting 33 ft monopole rated at 75 mph
but changed my mind when I found out what that required -
more than double the cost of a guyed monopole. Also building
it out of six foot sections instead of 12 foot sections reduced
the cost considerably. ME's probably understand why but, as a
EE, I was surprised.

Here's what the EZNEC manual says: "Horizontal wires should not
be placed exactly on the ground, but should be at least 1/1000
wavelength above (and in the case of EZNEC/4, also below) the
ground."

I posted a few months back about this problem and have narrowed down the root cause. The symptom are an overpowering hum at the low end of the am band. It's being caused by a 3-phase distribution line. I can follow this line in any direction for several miles any time of day with any of my vehicles and get the interference. I contacted the power company and supposedly they're going to look for the cause. Has anybody else dealt with this type of problem?

Source record: 55847

I took scrap pieces of aluminum tubing lying around, not being particularly careful of sizes as along they fit snugly into adjacent pieces when they were slotted. I used hose clamps. I made it 33ft and 3 inches tall (1/4 wave on 40). It has 32 radials of various lengths for the non-WARC ham bands 40 meters and higher. 16 of them are 34 feet long for 40. SWR on 40 meters is 1.2 to 1 without any adjustment at 7100. The vertical covers the entire band. I use a Palstar AT1500CV transmatch on other bands and run 700 watts when needed. I can work anything I can hear and I work tons of DX. The antenna is very quiet for a vertical. The Palstar has no problem matching this vertical on all bands 40 through 6 meters including WARC though 12 meters is the trickiest. Works much DX on all bands whenever I try Peter I Island, Kiribati, etc., though I use other antennas on bands other than 40 cut appropriately. Cost of the antenna was $0.00. I used scrap tubing, scrap #12 or thicker radial wire, leftover rope for 3 guys at 18 feet, leftover 4BTV base. This antenna has been up for months on a hill at 1100 feet and survived 80 mph plus gusts.

Hi Win,
I have little expereience with the different manufactures of HF switches. My experience is in relays for 1296 MHz LNA protection- and the port-port isolation is all over the board.

Ask the manufacturers if they have this spec.
Dale W4OP

That antenna is 5/8 wavelength on ~17.5 MHz. Above 21 MHz,
most of the radiation is lost at a high elevation angle.
Such an antenna is a poor performer on 15m, 12m, 10m, and
6m. Matching doesn't mean much for a monopole appreciably
longer than 5/8 wavelength.

I have an almost identical vertical with a relay controlled loading
coil I switch in for 160 and 80M and a SGC tuner.

Works great 160 to 30M.

Marginal at 20M and goes to poor from there up.

You should also contact the station managers at the AM stations you
listen to. Tell them where their signal is being interfered with, what
it sounds like, that it seems to be following power lines (if it does), etc.

If it is BPL having broadcasters not so happy about it could be a very
good thing.

If it's not BPL it should be fixed anyway and broadcasters have a little
more pull with utility companies than individuals. Lawyers on retainer,
ya know.

> be placed exactly on the ground, but should be at least 1/1000
> wavelength above (and in the case of EZNEC/4, also below) the
> ground."

Cecil, Probably the 1/1000 WL limit contains a safety margin.
This does not appear to be addressed by either the NEC 2,
or NEC 4 user manual.

Cebik's book "Intermediate Antenna Modeling", p 1-12,
states: "The minimum height for wires above
a Sommerfeld-Norton ground has two dimensions. The first
relates the height above ground limit to the wire radius.
The wire height (h) should be several times the wire radius
(a), that is, h>~a. As well, the minimum height is related to
the wavelength for the frequency in use:
(h^2 + a^2)^(1/2)>10^(-6)Lambda. If a is very small
compared to h, the wires may approach 10^(-6) Lambda
toward ground. ......reflection Coefficient approximation....
... the general recommendation is that ......
horizontal wires should be (>) 0.4 Lambda above ground".

Obviously, from the manual quote, EZNEC can invoke a
Sommerfeld-Norton ground.

Since I do not have GNEC I usually test my NEC 4 models
with NEC-Win Pro. Interestingly NEC-Win Pro actually
runs, with no errors, on below ground wires. The results
are usually pretty weird though.

Jeff,

This sounds like simple overload of the receiver by 60 Hz fields rather
than any sort of "interference", BPL or otherwise. I have certainly
observed this hum at times, and I suspect most people have.

For the most part power companies in the US are permitted to use 60 Hz
rather freely. There may be no chance for recourse.

It is possible that the 3 phases are not well balanced along this
stretch of line. One phase could be overloaded or close to overload.
That could lead to stronger 60 Hz fields. Power companies usually try to
maintain some degree of balance between phases, along with power factor
correction, but there are probably exceptions.

Thanks, Dale.

I will do that. So far, I have found, as you said, the claims are all over the board. In the data sheets I have been able to locate, I have seen numbers from 20db to 80db down. Something in the area of 80db would sure do the trick, if I can believe them, HI.

Correct Reg, Those are the parameters I used, with the
exception that the radials were also # 14 AWG (1.64 mm).

You raise some interesting points -- How do I measure
the radial impedance? I have to think; given a vector
network analyzer, how would I measure a radial system
under laboratory conditions? this is what I need
to replicate with NEC. Since I have never made
such a measurement, I am not sure where to begin.
Would it be valid to consider one radial wire as
an "End fed zepp", and feed one end with an
ideal transmission line? As long as I know the current,
and voltage at the measurement point, I can determine
the input impedance -- problem is; voltage input
with reference to what?

As for the reactive input; this is of little concern to
NEC since it drives the load from a complex
conjugate source.

So far as I have been able to determine NEC does
not provide the total radiated power, only the
normalized far field in peak "Volts" -- i.e. V/m at
1 meter, at every angular increment. Usually
every degree. I take these data to determine the
power density at each increment, and sum
over a hemispherical region; where I take the
elemental area to be:
(r^2)*sin(theta)*d(theta)*d(phi). Since the
pattern is symmetrical I only need 91 points.

Frank

Hank,

Just wanted to add that you don't need 1/4 inch wall stuff anywhere in a 33 foot vertical.

If you have it lying around you could use it, but the extra weight really isn't worth it. Same for reinforcing by thickening the tubing on the inside.

A hollow tube 2" in diameter with 0.058" walls is about 3 times stiffer than a SOLID 1" rod.

Now, strength and stiffness are two different things, but you're better taking the aluminum and making a fairly thin wall tube of large diameter if you're trying to make a strong, stiff element.

For the price of one 12 foot 1/4" wall 2" tube you can buy the whole vertical in 2" 0.058 wall tubing and the next telescoping size for joints.
1/4" wall would be good if you're going to guy it and put a tribander on top!

I'd go with Roy's vertical design, in fact. My antenna was a mess of found aluminum, tent poles, etc. Might have even been 7/8" now that I think of it.

This means that Roy's bottom section, if 0.058 wall 1.25" diameter 6061 was at LEAST 3 times as stiff as my 7/8" OD 3/4" ID 1/16" wall stuff, and that's assuming I was using a good, stiff grade of aluminum, which I wasn't.

Incidentally, Cecil, I think the 12 footers are more expensive because you can UPS ship 6 footers anywhere and can't do that with 12 footers... it may be that it's just cheaper to keep the 6 footers in stock because the market is bigger. Could also be that it's cheaper for TX Towers to get them in .... dunno. It's too bad though, 12 foot continuous sections would be good for this sort of thing.

73,
Dan

Frank,

So NEC4 cannot calculate input impedance of the radial system and we have almost reached a dead end.

Would it be possible to insert a loading coil (2.48 uH) at the bottom of the antenna to tune out its input reactance (which is what my program does.)

Then repeat the efficiency calculation and tell me what you get.

Reg.

Lets face it folks to be a well rounded Ham one should learn CW. You never know when it will come in handy. I am not that good at it, maybe a step or less above a Novice, but I like to fool around with it. One ought to think about learning it in do time even though it is not required.
My 2 cents worth.

Those with an interest in building a Wellbrook ALA 100 setup for use on an antenna rotator may want to check out my most recent blog entry (July 22nd). I have pictures and construction details that describe the way I approached the project.

I believe the ALA 100 is the most flexible and useful Wellbrook model for the do-it-yourselfer. You can construct the loop in whatever manner suits your abilities and requirements.

My use of the ALA 100 is primarily for DXing foreign medium wave signals, with a secondary use of hearing third-world broadcasters on the tropical bands. I've heard of some amateur radio operators using Wellbrook antennas for a receive-only solution, too.

I am considering building the Louisiana loop shown in this month's QST. It is basically an inverted delta loop. I don't know if I can model it on EZNEC (I guess I can...but I've only progressed through a dipole or two).

I actually intend to string it up among some trees in the backyard in a sort of temporary fashion.

Realizing the directionality involved, I will aim it toward Asia over Alaska.

Now, any caveats or recommendations or ? before I embark on my first antenna build?

I don't at present even know the feedpoint impedance but I intend to use RG8U for feedline if that's possible. There is no mention of an UNUN or Balun in the article.

What do youse think? Thinks?

Sound like why I bought a copy of MultiNEC. The Excel interface allows me to "sweep" the values of any parameters. I start coarse, and 2-3 sweeps allow me to narrow down and optimize f/b and swr. By writing some Excel extensions, you could have this done semi-automatically.

I've done this for some circuit design programs, where they look up and use standard component values.

Howsoever you do it, remember to check your final figures for sensitivities by putting in reasonable measurement tolerances, or you may end up with a theoretical result that just won't happen.

Hi John, The model does not account for the metal tower right in the middle of the delta loop. It will have some effect on the feedpoint impedance, as well as the pattern.

If I were to string it up among trees, I would go with a standard (not inverted) delta loop configuration. According to the article, it gives about 1 db more forward gain at an elevation angle that might favor dx. You won't have to worry about a tower messing things up either.

As for feeding the loop, consult the ARRL Antenna book for the various methods. For a single band Quad or delta loop, I would use a series transmission line matching transformer. Thats what I think.

Hi Reg,

I'll admit to being away from rraa for quite a while. A good bit of the time away was while finishing the writings for Reflections 3, which includes several new chapters, some of which archive a portion of my escapades in designing antennas for various spacecraft, including those that flew on the World's first weather satellite, TIROS 1. I was fortunate in being at the right place at the right time when the space age began. Those were the years I spent with Jess Epstein, the 'E' of the BLE team. Some of the additional material that went into Reflections 3 is available on my web page at www.w2du.com. I think you might find Chapters 19A and 21A of interest.

From eavesdropping on the banter between you and Richard C it's easy to see that your winery has kept your mental physique it top shape. I hope that your physical physique continues at least in its present condition.

Getting now to BLE, I agree with you concerning the changes in ground characteristics at HF compared with MF and LF. I don't know if you have a copy of BLE, but you should know that the BLE experiments were performed at 3 MHz. Please let me know if you have BLE, because I'd like to email you a copy if you don't. It will demonstrate the hundreds of measurements taken meticulously to arrive at the conclusions reported in their paper of 1937.

Of the many results of various combinations of radial lengths and numbers of radials, the one that that stands out in my mind is the combination of the longest radial, 0.412 lambda, with the maximum number or radials, 113. This combination achieved near-perfect ground, yielding a field strength of 192 mv/m, as compared to the theoretical maximum of 196 mv/m, achieved with perfect ground. The reference for these numbers is 1000 watts delivered to the antenna and measured at 1 mile. Notice that the difference between the ideal and actual field strengths is only 2 percent.

Reg, concerning the difference in ground characteristics with frequencies above 3.5 MHz, please consider this. When the radials are long enough, and enough of them spaced sufficiently close, the effect is that of nearly perfect ground, regardless of the actual ground characteristics beneath the radials. Let's consider a comparison. First, few radials widely spaced. Displacement currents reach the ground everywhere surrounding the vertical radiator. Currents entering the ground between the radials diffract toward the nearest radial of higher conductivity. During its travel toward the radial it naturally encounters the resistance of the ground. However, with many radials more closely spaced, currents now entering the ground have a shorter resistance path in reaching the nearest radial, approaching a negligible value.

My point is that when there is a sufficient number of radials of sufficient length to approach a nearly-perfect ground, the ground characteristics beneath the radials are irrelevant within the area they cover in determining the terminal impedance and efficiency of the radiator. Therefore, the different gr ound characteristics that prevail as the frequency increases above 3.5 MHz are also irrelevant. This is not to say that the ground characteristics away from the immediate area are not important.

You might get a chuckle concerning the number of radials being 113. The original plan was to plow in 100 radials. When the grunts Jess Epstein and Bob Lewis had plowed in the intended 100 there was wire left over on the spool. They asked Brown what they should do with the remaining wire, he said, "Plow it in." The remainder of the wire allowed just 13 more radials to be plowed in.

On a personal note, I engineered and built WCEN in Mt. Pleasant, Michigan, 500 w on 1150 Kc (it was 'Kc' then), with a 300' Blau-Knox tower. I plowed in 120 radials. My Dad manufactured the plow, which I rode, while he drove the tractor.

Hope this keeps ya busy fer a while,

Walt, W2DU

Keep in mind, also that the high tension lines are
NOT necessarily owned (or even controlled by
utilities! Further, some of these are feeders for
the interstate power grids, in the U.S./Canada.
For example, B.P.A. , or Bonneville Power
Administration, is a Federal agency, generateing ,
and selling their power to various utilities.
One, that I have had experience with is the 500KV line
they ran to Malin, Oregon, from the Columbia River
dams! A telephone line paralleling it for about 4
miles, could measure 400 Volts of Escape
(induction) at a office 25 miles away! Also, many
of these are D.C. (not A.C), to avoid the
situation just described (power loss via
radiation/induction)- these can run hundreds of
miles! There can be other things also, can cause
problems with open wire circuits paralleling
broadcast stations (yeh, I Know, it ain't supposed
to happen, especially in transposed circuits)!
In sum total, you may have to investigate just
WHO owns this line, and contact THEM- Your local
utility may have little to do with them- except
use the energy they supply! Jim NN7K

By taking the test you're claiming that you understand the questions
and know the answers. By memorizing the answers you're not learning
enough to understand the questions.

But I wouldn't expect you to understand what "honesty" means.

>how balanced is to to place CW over all over ham knowledge?

No one is, any more than by requiring people to know the law one is
putting the law "over all ham knowledge".

>How progressive is it?

How progressive is it to not require people to know ... oh, yeah,
that's progressive, since the new thing is to hand out licenses
because people have some kind of "right" to get on the air.

>how loyal is it to denny the nation the benifits of allowing more
>operators

What "benefits" does the country get from more people using radios who
don't know the first thing about them? (Whatever "denny" means.)

> to aquire the expence needed to truely work on hf

You don't acquire knowledge (which is what's needed) by playing with a
radio.

>how patriotic is it to keep a staion forom aquiing the skill to be
>ready for service to conutry and community?

How does playing CB on the ham bands give one "the skill to be
ready for service to conutry and community"? Or any skill, other than
getting what you want? You don't acquire skill by doing something
that requires no skill. And you, particularly, don't acquire
knowledge by demanding something for nothing.

Frank,

Alternatively, or in addition to, you could shift frequency nearer to 8.3 MHz where the antenna is resonant and its input reactance is zero.

And again do the efficiency calculation. Tell me what the efficiency is and the frequency. Also the antenna input resistance.

You will see I am desperately trying to localise the discrepancy in efficiency. It is either in the radials or in the antenna. You should also learn something about NEC4.

Reg.

you statement makes no sense since obviously anyone that has a radio
and can turn it on knows at least the first thing ,if he/she can get on
the air he know a few more
>
> > to aquire the expence needed to truely work on hf
>
> You don't acquire knowledge (which is what's needed) by playing with a
> radio.
knowledge is needed why? It is helpfull I grant you but needed vs
experence
well that is Bullshit I know more I supect about radio and RF than you
having studied EM waves and their proerty at the College level and yet
this knowledge is only mildly usefull if I am on the HF bands as I
often am for Feild day or something to be a more effective operator I
need expernce at HF not knowledge of circuts
>
> >how patriotic is it to keep a staion forom aquiing the skill to be
> >ready for service to conutry and community?
>
> How does playing CB on the ham bands give one "the skill to be
> ready for service to conutry and community"?
what is playing CB mean? other than then pejoritive
>Or any skill, other than
> getting what you want?
babble all you like
> You don't acquire skill by doing something
> that requires no skill.
so you are claiming this is NO skill in passing traffic at HF I think I
could find people that woluld disagree with you
> And you, particularly, don't acquire
> knowledge by demanding something for nothing.
no knowledge is aquired by learning Morse Code certainly no secert of
the unverse is derived for it

No one is suggesting that ANYONE be given something for nothing
but it is a requirement of law that restictions in access to PUBLIC
reasources must be reasonable in nature

knowledge of Morse code is not realected to prevelegdes it brings ask
the Armmy how many CW opperators it uses in routine affairs, the answer
is zero (intel is not for this prupose routine nor is specail ops)

Hi Robert,

The shortest line would have the most gain. However, in all
practicality, if you are not talking a great distance, it doesn't
really matter much for receive from an antenna suited for the band you
are listening to.

Dear Walt,

At risk of upsetting a great number of patriotic USA citizens, all BLE hero-worshippers, I admit to having speed-read BLE's lengthy paper some years back. Their conclusion, that with a sufficiant number and length of radials the ground characteristics are irrelevant, is so glaringly apparent they could have stayed in their offices and saved a great deal of expense and copper wire. I am reminded of John Cleese's remark "They must have had first-class honors degrees in stating the bleeding obvious".

Because BL&E omitted to measure ground conductivity and permittivity on the site their conclusion amounted to making a virtue out of a vice and Marzipan the Magician's magic number of 120 came into existence. Their sponsors should have made them go back to finish the job.

In the absence of any other information at the time, the fact of irrelevance was of interest to LF and MF broadcasters with money to burn, but it was, and still is, of no use to radio amateurs, confined to the HF bands with limited purses, small back yards and XYL's to keep happy.

My small program Radial_3 has been singled out and I have been accused of disagreeing in a disruptive, almost criminal manner with BL&E's conclusions. This is patently untrue! The program has nothing to do with BL&E except that it deals with a similar subject in terms appropriate to amateurs and draws its own independent conclusions.

Your absence caused a little worry. Glad to hear you were only working.

Reg.

What equivalent conditions? Where can they be found? What was the ground resistivity and permittivity on BL&E's site?

I am not motivated to do anything except reply to your remarks. You are making a song and dance about it.

If anybody wishes to confirm or deny the usefulness of program Radial_3 then all they have to do is do what I have done and bury a few (not 120) wires in their back yard and get on the HF bands.

Proof of the pudding lies in the eating!

I'm often confronted with problems as a physicist where one can only get a handle on upper and lower bounds.
Lower bound:
I'd say the minimum number and length of radials is 3 (must define a plane) and 1/4 wavelength (satisfies boundary conditions).

Upper (infinite sheet of copper)
As Walt and Reg have debated, the "Cleese extreme" (to steal from Reg's post) is trying to duplicate the "infinite perfectly conducting plane" of our elementary physics books.

Who knows? That's not what Mark is talking about, is it?

> Or any skill, other than
> getting what you want? You don't acquire skill by doing something
> that requires no skill.

So it really is all about CW. Why have a written Exam at all?

> And you, particularly, don't acquire
> knowledge by demanding something for nothing.

The requirements for an amateur radio license have been all over the
map over the history of the service. The ORIGINAL amateur radio
license had no Morse Code Exam, even when Morse Code was the only means
of communicating.

Get over it. Everyone else is moving on.

Yes Adam, a logical way of looking at it.

Associated with any number there is always another number which is sometimes, but not often enough, used to describe its uncertainty.

But nearly always it takes much longer to determine the uncertainty than it does to arrive at the first number, especially if the first number is the result of a measurement.

Reg.

Reg, I appreciate your worry about my absence.

However, concerning the 'obviousness' of the conditions when there are enough radials to simulate perfect ground, you must remember that it was not 'obvious' in 1937. Prior to that time most BC 'aerials' were in the form of a 'T', a horizontal wire (top-hat loading) supported by two towers, dangling a vertical wire (the radiator) from the center, down to the antenna tuner. The 'ground' system was a wire counterpoise, because very little was known about any other type of 'ground' to work the vertical against.

Brown originated the concept of radials to improve the conductivity (meaning reducing the resistance) of the ground, simply to avoid the construction of a messy arrangement of wires to get tangled up in. But before presenting the suggestion of radials to the world he proved it would work by performing the BLE experiment.

Brown also is responsible for the tower antennas being of uniform shape over its entire length, where before it was customary to use the diamond shape. With the diamond shape the field strength measurements didn't follow the theory. Using models for measurements he determined that the current on the diamond shape does not flow uniformly, which resulted in undesirable radiation patterns. He then demonstated that when the tower construction was of uniform cross section the current became uniform and the radiation patterns became uniform and more predictable and useful.

After proving the concept with models, he worked with John Leitch, chief engineer of WCAU Philadelphia, in proving that it worked with full-size towers. The WCAU tower was diamond shaped. The experiments with WCAU, and subsequently with a tower of uniform cross section, proved the concept to be correct.

The result of Brown's experiment with the shape of the tower is that as of 1940, the FCC mandated use of towers with uniform cross section for all new installations. In addtion, no changes of any kind in the transmitting system were permitted in stations that didn't already have a tower with uniform cross section until the present antenna system was changed to one having uniform cross section. Brown's influence on BC antenna systems is legendary. He also patented

the concept of using loading coils to shorten the physical length of towers. Some towers that followed his lead have insulators between sections and an inductance connecting them.

Brown's article, "Directional Antennas," appearing in a 1937 issue of the IRE, formed the theoretical basis for all directional BC antennas

Brown also invented and patented the ground plane antenna for VHF and UHF. All of his antenna experimentation was as an engineer with RCA. It was a great experience for me to have worked in Brown's antenna lab along with guys like Jess Epstein, O.M. Woodward, and Donald Peterson.

These are very good points. I am reading these postings to try to
understand the behavior of actual implementations that lie somewhere between
the extremes you pointed out. In other words, what gets you the most bang
for the buck.... How fast does performance change with increased radial
length and number of radials.

Depends.
You could just keep adding radials when you can afford more copper until
things stop improving.
(Whatever "stop improving" means to you.)
Copper's expensive.

My SteppIR vertical is on an aluminum roof.
(Just my approach to the problem)

And Walt's right.
What is trivially obvious to us wasn't so in 1937.
Maxwell's equations weren't 100 years old yet.
It had only been a few years since Gibbs wrote them in the modern form we
use.
Radio was barely understood by only a few people.

Hi OM,

In fact, how "many" people knew is immaterial to what was known a good
twenty five years before the BLE paper.

From my "Standard Handbook for Electrical Engineers," 1912,
Sec. 21, Radiotelegraphy, Method of Exciting the Antenna, part 283
Antenna Ground Connections:
"The outward and inward movement of the lines of electric force
during the oscillations in the antenna give rise to earth
currents. These earth currents are most intense in the immediate
neighborhood of the antenna, and if the earth is a poor conductor
a large waste of energy ensues. To guard against this loss, a
radiating network of wire is place beneath and around the antenna.
In the case of a flat-top antenna, the radius of this wire net
should not be less than the length of the horizontal portion of
the antenna."

I shouldn't have to point out that a handbook is not the place where
new science appears, but where tested science is aggregated. Earth
currents, screens, and lost power were not unfamiliar a century ago.

What is "Bleeding obvious" about the BLE paper, is that it puts
numbers to the quoted paragraph above in the face of its mocking:
>>At risk of upsetting a great number of patriotic USA citizens, all BLE
>>hero-worshippers

It is quite evident that the merit of the BLE paper serves the true spirit of Lord Kelvin, and that in the context of this group, it is USA citizens who honor his precepts in the face of this last piece of British trolling of Reggie's who is more interested in juvenile posturing than celebrating his heritage's expression in a fine work.

Therein lies the solution to the problem. Make A1 the
only mode allowed within amateur radio - solves all
the problems, doesn't it? No more mode arguments, no
more band crowding, no more expensive equipment, ...
The list of advantages is virtually endless.

What is the uncertainty of the uncertainty? If the uncertainty is a number, then, "Associated with any number there is always another number which is sometimes, but not often enough, used to describe its uncertainty." You're going to end up with an infinite string of uncertainties if you keep this up, Reg.

Spiral concentric or coil will change the pattern but since the antenna
is so electrically small it won't make much difference unless you want
to use the nulls. I would expect that a coil wound would be best. I you
are concerned about using a null in the antenna pattern then go one turn.

Reg, According to NEC 4.1 the input impedance is near 40 ohms
(39.9373 + j 0.394926 ohms) at resonance (8.07 MHz). With
100 W input the total radiated power computes to 31.8 W. I am
continuing with checking the program to be certain I have not made
an error, and also working on a NEC solution to the input impedance
of one radial. Note that the computation also includes copper loss,
which should be insignificant. I have also included a copy of my
code below.

==========

That's exactly what program RADIAL_3 is intended to help you with.

All the user has to do is convert radiating efficiency into bucks. The higher the radiating efficiency the more bucks it will cost, the greater the length of wire, and the more painful the back ache.

It's a matter of diminishing returns.

Thanks, Dan. I see that now and I think I'll start with 2" diameter
tubing in 6' lengths and taper down accordingly. I do get some serious
wind here from time to time.

Thanks to all who responded; I'm moving forward with considerably more
confidence in the outcome..

> ----
> Reg.

Reg, I have completed a "Ball park", preliminary estimate of the
radial impedance.

Given an antenna with one radial, I computed
the input impedance of the monopole alone, over a perfectly
conducting ground. The antenna input impedance, at 8.07 MHz,
is 36.21 - j 3.1. Adding one radial, 25 mm below ground, with
parameters Er = 16, resistivity 150 ohm-m. The input impedance
becomes 149.2 + j 17.9. Subtracting the antenna impedance
gives a radial impedance of 113 + j 21.

These results are not too far removed from "Radials_3", which
gives the antenna input impedance of 33.79 - j 24.8, and radial
input impedance of 84.2 ohms. Under these conditions,
integrating the power density, shows a total radiated power, with
100 W input, of 8.8 W, or 8.8% efficiency. There appears
to be a significant difference, in the computed efficiency,
between Radials_3 and NEC 4.1. Radials_3 calculates
the efficiency as 28%.

Note that with one radial the radiation pattern exhibits a slight
asymmetry of less than 1 dB. Since I have assumed perfect
symmetry of the radiation pattern a small error will be evident
in the above computation.

Testing my method of integration, on a lossless monopole, over
a perfect ground, shows a 1% error; i.e. for 100 W in, the
total radiated power = 101 W.

Regards,

Frank

Help. I've been licensed since 1967, but I haven't been active for about 20 years. I just bought a FT-101EE with a Cushcraft R4 vertical antenna, however there are restrictions in my subdivision about antennas. I'm thinking my best bet may be a long wire between my house and a neighbor's tree with a tuner. I know this is an ago old battle, any ideas for an inconspicuous HF antenna?

>> because people have some kind of "right" to get on the air.

>Then why is it with the prospect of losing the CW Exam, that you'se
>guys want to "beef up" the written exams?

We don't. We want to get back the level it used to be before it was
dumbed down to the point that you could almost pass it if you never
heard of the FCC, ham radio or electronics. Just by guessing at the
answers. It used to require that you draw (was it 3?) schematics.
From scratch. Let's see how many people could do that today. A

Colpitts oscillator, a Hartley oscillator and some other circuit that
I've forgotten at the moment. They're still as relevant today as they
were 50 years ago.

>> >how loyal is it to denny the nation the benifits of allowing more

>> don't know the first thing about them? (Whatever "denny" means.)

>It's always been that way. You could even buy Heathkits already
>assembled.

But you had to actually *know* a little theory to use one legally.
Today all you need is the time to take the test and the money for the
test and the equipment. IOW, a CB "license" with a tiny bit of
annoyance up front. How does CB benefit the country?

>> You don't acquire knowledge (which is what's needed) by playing with a
>> radio.

>Then the military has wasted billions of dollars over the years
>"training" radio operators.

I trained operators when I was in the military. We didn't do it by
giving recruits radios and telling them to go jam each other.

>> >how patriotic is it to keep a staion forom aquiing the skill to be
>> >ready for service to conutry and community?

>> How does playing CB on the ham bands give one "the skill to be
>> ready for service to conutry and community"?

>Who knows? That's not what Mark is talking about, is it?

That's exactly what he's talking about. Give someone a radio and a
"license" to use it and he'll "acquire the skill to be ready for
service to country and community". That's what Mark said, right up
above. How does one acquire skill by playing radio?

>> Or any skill, other than
>> getting what you want? You don't acquire skill by doing something
>> that requires no skill.

>So it really is all about CW. Why have a written Exam at all?

You don't acquire technical skill by doing something that doesn't
require technical skill. You don't acquire operating skill by doing
something that requires no operating skill. And you don't acquire
skill in CW by cursing into a mike.

But that's what Mark and his ilk want - we'll have "skilled operators"
if we allow people to buy radios and put them on the air with no skill
or knowledge. By osmosis? Or by magic?

>> And you, particularly, don't acquire
>> knowledge by demanding something for nothing.

>The requirements for an amateur radio license have been all over the
>map over the history of the service. The ORIGINAL amateur radio
>license had no Morse Code Exam, even when Morse Code was the only means
>of communicating.

So you'd get a license not knowing CW, build a radio (you couldn't buy one then) and ... what? Sit and look at it. Some things are just too obvious to need mentioning.

>Get over it. Everyone else is moving on.

Evidently not, or I'd be the only one in the world advocating that a test should actually test for something. There are actually millions of us who don't think lack of instant gratification is the worst thing in the world.

What next? DXCC awards for those who *want* to work 100 countries?

The disadvantages are too. No playing with digital modes. No
innovations. No new inventions by hams. And, I have to admit, my CW
has gotten a bit rusty - I doubt I could send readable code at much
over 15wpm these days. I can still copy faster than that, though.

meaning no need for a CW test?
> You don't acquire operating skill by doing
> something that requires no operating skill.
no need for writeen test either thn?
> And you don't acquire
> skill in CW by cursing into a mike.
who siad you did

but I for one have no interest in learning CW at all even if that were
possible for me (which I do not believe is the case bt that is another
arguement)

you OTOH seem to think it polite to disparage opertors that you likely
have never heard
>
> But that's what Mark and his ilk want - we'll have "skilled operators"
honestly in time if we did give the license away the user would
develope skill with it
> if we allow people to buy radios and put them on the air with no skill

on here there are perhaps 3 people still advocating a Morse code test

OTOH nobody advocates ywe drop testing except occasion the frustrated
advocate of Code testing

Yes personalyI think some the thing we current test are at best
questionable I would prefer to foucs more on rules and safety question
I realy don't think any body needs to memorize thatwhat freg is white
in SSTV signal he know prehaps where to look it out but to have that
knowledge memorized no way and yet there is such a question on the
current extra pool
> There are actually millions
> of us who don't think lack of instant gratification is the worst thing
> in the world.
what has that got to do with maintining your frat house game called
Morse Code testing?
>
> What next? DXCC awards for those who *want* to work 100 countries?
who cares about a DXCC award? I certianly don't realy

or does not caring about working "countries that have no people in them
and sometimes barely exist at high tide make me not a ham either

1079. Re: Length & number of radials

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-23 23:30:42 UTC
From: hasan schiers <schiers@netins.net>

Source record: 55816

Thanks Richard...however the info you present doesn't deal with the real issue that has been raised by Reg's program: (you are adressing another area of possible disagreement)

Do 26 radials 5 metres long perform substantially as well as 26 radials 16 metres long at 3.62 mhz with the two soil constants = 25 (in my case), with radial wire size #14 and antenna wire size #10 (I think I used 2mm and 4mm in my calculations.)

The issue has never been (for me) how closely does Reg's program match a 1/4 wave vertical with standard length radials. The "real" question is does Reg's program accurately reflect the performance of vastly shorter radials than the typical "wives' tale" (Reg's characterization) 1/4 wave length radials.

I have always accepted that some shortening of earth based (on or under) radials (below the assumed 1/4 w or longer as in BL&E) was acceptable. The problem is, Reg's program allows incredible shortening, predicting high efficiency at the same time.

I have a 1000' of wire left to put down. If Reg is right, I can put down 66 radials 5 metres long and get outstanding surface coverage. If more "orthodox" texts are correct, then I should stick with 16 metre (approx 50') length and then I can only put down 20 more radials than the 26 I have now.

Let's not get distracted (although your point for the 20 degree antenna shows yet another departure from BL&E).

Here's the fundamental contradiction between Reg's program and the orthodox approaches:

==========
Reg says (given the values I have stated above), that 5 metre long radials will peform (substantially) as well as 16 metre long radials, all other things being equal. Thinking this makes my head hurt.
==========

BL&E seems to contradict this (although I haven't found the precise comparison I'm looking for yet).

Tom, W8JI's, measurements seem to contradict this.

NEC-4 should be able to tell us how much current is in a radial and how that current is distributed along the length of the wire. If it disappears into inconsequential levels within the first 5 metres, then it confirms Reg's assertion. If it does not, i.e., it remains at substantive levels well beyond 5 metres, then it contradicts Reg's program, and agrees with BL&E, as

well as W8JI. (I thought NEC-4 could do this problem, maybe my assumption is completely wrong.)

==========
If NEC-4 can't do this "current along a radial" analysis (buried or on the surface, take your pick), then we need experimental data that shows us the same thing: how fast does the current along a radial decrease to inconsequential levels. If it is within the first 5 metres, Reg is right. If not, he's wrong. It's as simple as that.
==========
Why is it so hard to get this answer?

hasan, N0AN

Sounds to me like you already have a workable idea in mind. Just use
small wire, keep it high enough to be out of reach.

Use a tuner, and keep your coax as short as possible (lossy with high
SWR) and you should be just fine.

Frank,
Thanks for information so far. I need time to study it.

Could you tell me the

efficiency,
antenna input resistance component
and resonant frequency,

using our standard set of input data, ie., 36 radials, 10 metres long,
when frequency is set exactly to its 1/4-wave resonant value around
8.3 MHz. Input reactance = zero or very few ohms.

Thanks.

Reg.

P.S. Sorry, my bad. A lot of things have changed since I started on the Arpanet in 1967. I'm pretty sure the rules on the Arpanet prohibited using newsgroups that way.

Yep, it was a lot different back then. Even when I got into it in the
80's. The signal-to-noise ratio was much higher. Only a handful of
newsgroups...no trolls...no spam...not even any www...sigh...

the problem was somebody one of the area newer hams was mistaking my
jt65a signal for badly sent CW he came on the reptear later and asked
if anyone who sending the realy bad on 144.111 and I called him on the
repeater explain I was trying moonbounce and he was tepping on the
echos I was trying to read bso then he cleared off and 8:35 eEDT I made
EME contact with IK7EZN

I gotta say, this is one of the cleverer troll posts I have seen !

I'm going to no-sell it and say that I've got this damn noise around
50.175 that sounds just like weak SSB if you're tuning by it, and so I
get all excited when I'm tuning around 6m and I come across it... until
I look at the display.

Also have a bunch of them that sound like CW signals... this is mostly
a problem on 6m where I'm really, really hoping something happens.

73 es you'll get over it someday,

Dan

Move.

If you signed an agreement not to put up antennas, don't. Hams have a
bad enough rep with the neighbors as it is without violating
agreements they voluntarily agreed to.

> BB> (CM4228)

I did it years ago with a 4-bay bowtie -- lighter, obviously, than your 8-bay, but I had not a bit of trouble over several years.

I was at Ft. Meade, MD, near Baltimore. I connected two antennas in the attic -- close, so they'd interact -- one VHF aimed toward DC and one UHF hanging upside down on a rotor. I rotated for UHF as needed, and used the UHF antenna to cancel ghosts on VHF. The whole stupid thing was a success the first time -- entirely by accident. I had envisioned a WHO-O-O-LE lot of trial-and-error, but none was needed. And the rotor did not die in about two years of daily use.

This antenna was meant to be fed as a multiband antenna using open wire
feedline and a tuner.

Its height dependent. The takeoff angle on 20 is high. I myself would
use a dipole with open wire feedline. However the authors intentions was
for a compact multiband antenna. If you have trees use the large loop
as in the ARRL antenna handbook.

For a better antenna that feeds with open wire line and that has a ideal
low angle pattern on all band from 20 meters to 10. Look at the
horizontal magnetic slot antenna. You can find details in the latest
RSGB handbook.

A good tuner for these antennas is the Balanced Tuner by Measures.

> constants = 25 (in my case), with radial wire size #14 and
> antenna wire size #10 (I think I used 2mm and 4mm in my calculations.)

Some insight into this is provided by the following.

Figure 37 in the BL&E paper shows about 77.5% of the theoretical maximum inverse field for a 77 degree vertical used with 30 radials of 0.137-wavelength each.

Figure 36 shows 90.6% of the theoretical maximum inverse field for the same vertical with 30 radials of 0.411-wavelength.

For 30 each 0.137-wavelength radials and a 77 degree vertical, Reg's program radial_3 calculates an efficiency corresponding to 87.2% of the theoretical maximum inverse field. (Other parameters for radial_3 were as shown in the plots I posted earlier.) This is significant when considering that the inverse field varies by the square root of this power difference.

> NEC-4 should be able to tell us how much current is in a radial
> and how that current is distributed along the length of the wire. If it
> disappears into inconsequential levels within the first 5 metres,
> then it confirms Reg's assertion. If it does not, i.e., it remains at
> substantive levels well beyond 5 metres, then it contradicts Reg's
> program, and agrees with BL&E, as well as W8JI.

BL&E data show that if few radials are used they may as well be "short," because system performance isn't improved greatly by making them much longer. Quoting the BL&E paper (p.760), "These diagrams show that the ground system consisting of only 15 radial wires need not be more than 0.1 wave length long, while the system consisting of 113 radials is still effective out to 0.5 wave length.

But there was no experimental evidence from BL&E showing that radiation efficiency ever _improved_ with shorter radials, as apparently calculated by radials_3..

Are ceramic variables available??

The reason variable capacitors are used is that variables can tune the loop to resonance.

Wayne,

The best study I've seen is in both the ARRL Antenna Handbook and in ON4UN's Low Band DX'ing Handbook. I think it was a 3 station that came up with a method (consistent with BL&E) that gave a simple formula for putting down the optimum number and length of radials, for a given length of radial wire available. I used that study to originally arrive at 50' long radials at 80m. This gave tip to tip separation of about 3 or 4 feet on 80m, which met his criteria. The material above specifically answers the question: how do you get the best bang for the buck for a given amount of available radial wire.

Read that material..or at least get the formula and apply it to your available wire...that will get you were most of us are with respect to optimizing radials.

Now, Reg has come up with his program that flies in the face of these other studies, indicating one can obtain comparable performance with MUCH shorter radials (5 metres instead of 16 metres) and that is what started this whole thread. We await some sort of comfirmation from several sources that Reg's numbers are correct. If they are, Reg will become famous.

Currently here is how things line up:

1. BL&E doesn't seem to agree with Reg's numbers (on the issue of short radials)
2. Tom, W8JI's, recollection of his measurement don't either.
3. NEC-4 is in the process of analyzing the short radial comparability claim as we speak.

The entire issue is: does the current in the radials described above taper off as quickly as Reg predicts, or not? If it does, the short radials will be comparable and Reg is right. If it doesn't, Reg needs to fix his program in that particular section.

We await more data, or someone to extract from BL&E a precise answer to the actual question: how fast does current fall in a radial as you move away from the base of a 1/4 wave ground mounted vertical with shallowly buried radials.

In the mean time, you can get started with the formula I referred to above. If Reg is right, you used more wire than needed. If not, you have your wire in place and are ready to go.

Hello, this situation is very simular to mine. I have tried a lot of
different ideas and LW's are very good stealth antennas BUT:

From my own experience:

1: Need good RF-ground close to tuner. I use radials.

2: Tuner is best located well outside of shack or you will run inte problems
with RF and/or antenna picking up noise from the house. For practical
reasons this is solved with a remote control or an autotuner.

Right now I use a 6m (20ft) "El Cheapo" fishing rod vertical with a wire
inside. My tuner will tune it from 80 to 10m. This is very "stealth" if you
can hide the radials. Burry them in the lawn at a dark night. This is of
course not a very efficient radiator at 80m but has worked ok with 100
watts. I use about 100 ft coax to tuner to keep it away from house.

There are posibillities....

SM0FKI / Ulf

> is the "ohm", except by memorizing?

More importantly, that you can only transmit on 7.000 to 7.300 mHz, with restrictions on mode and license class. Or that you call "MAYDAY" on voice or SOS on CW for emergencies and never, never, never call "breaker, breaker".

Going back to the orginal point of memorizing or not, is knowing the type of oscilators and drawing their schematics anything but memorizing?

Actually, the only MORSE code you need to get help is SOS (not even run together as one letter). If you keep sending SOS, SOS, SOS, someone will eventually hear you and track you down.

Note that the original intent of the morse code test was that amateur radio was to provide a pool of ready trained radio operators in case of war. I'm in a country in the middle of a war, and I can guarentee you that NONE of the radio communications are morse code.

In fact, until we took out the cellular towers in Lebanon, almost all of the Hizbolah's command and control traffic was via cellular phone.

Geoff.

---------- REPLY SEPARATOR ----------

You didn't give many details such as the bandwidth of the antenna, but
if you use the NP0 type ceramic capacitors you should be ok. Loops,
especially small ones, are notorious for narrow bandwidth and stable
caps are a must.

Are you suggesting that the OP might actually want to comply with the
terms of the contract he made when he bought his house?

How strange!

Not knowing the "distances" involved - any chance they may be using YOUR
cell towers? IF so, that could really suck. Nothing like having your enemy
use your own equipment against you.

Lou

If you bought the house knowing that antennas were not allowed, consider not
putting antennas up, at least outside. If you got sucked into the deal by
an unscrupulous builder who deliberately hid the antenna restrictions so
that he could sell a house (this happened to me a few years ago).....

OK, stealth antennas...obviously higher frequencies are easier to deal
with....
1. Flagpole converted to antenna
2. Horizontal loop around the outside of the house, in the attic, or around
a room.
3. Mag loop
4. If you park your car in the driveway, mobile antenna with coax reaching
to shack.
5. Ground mounted tilt up vertical
6. Tilt up vertical mounted on metal fence
6. DDRR
7. Small diameter wire end fed
8. Capacity hat vertical with loading coil near top, producing a short
vertical not easily visible
9. Attic dipole

1112. Re: Length & number of radials again

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-24 15:44:39 UTC
From: hasan schiers <schiers@netins.net>
Message-ID: <ea2pt9$bv7$1@news.netins.net>
Source record: 55699

Preliminary numbers from Frank's NEC-4 run on Reg's model below:

Caveat: I have not been able to ask Frank if the segments are all the same length along the radial wire. The info below is based on that assumption.

The radial is 10 meters long, buried about 1 inch. I'm reading the numbers from the graph that Frank sent me. The radial wire is 40 segments long or .25 meters per segment. The antenna is 9 feet long and modeled at 8.07 mhz.

If I'm reading it right, at 30 segments along the radial wire, the current has dropped from a peak of 0.6 amps to 0.2 amps. 30 segments seems to be 7.5 meters out. If the current is still 0.2 amps at 7.5 meters out on a 10 meter radial, then Reg's approach fails. He indicated 20 dB down at a short distance out. 75% of the way out on the 10 meter radial, the current is down 0.2/0.6 = .33. 10log * 0.33 = 4.8 dB (if I did that right).

So...it seems that the current along the radial is down only 4.8 dB at 75% of it's length. Reg indicated that it should be down 20 dB at about 1/3 of its length.

At the 35th segment of the radial, the current is 1/6th or 7.8 dB down. This is at 90% of the radial's length.

At the 39th segment of the radio the current is .025 amps. 0.025/6 = .0146. 10log * .0146 = 14 dB down. That is only 14 dB down at 100% of the radial length.

I'm using 10 log * (I1/I2) for for the dB calcs...I think current ratios and power ratios are 10log, and voltage is 20log.

It is possible I'm interpreting Frank's graph incorrectly or applying the attenuation that Reg refers to incorrectly. I'm just so glad to see some numbers for current distribution along a radial wire from NEC-4, that I had to post what I see.

Eyeballing it looks like this:(the radial wire starts at segment 39 and runs to segment 79)

Segment 39 0.60 amps, distance from source = 0, dB = 0
Segment 49 0.54 amps, distance from source = 2.5 meters, dB = 0.46 dB
Segment 59 0.42 amps, distance from source = 5.0 meters, dB = 1.5 dB
Segment 69 0.22 amps, distance from source = 7.5 meters, dB = 4.3 dB
Segment 79 0.025 amps, distance from source = 10 meters, dB = 14.8 dB

What does Reg's program predict for dB down on this sample antenna?

Using 25 and 25 for soil and the info Frank gave me:

Reg's program shows radial attenuation of 20 dB at 2.3 meters from the source.

Side by side with the NEC-4 data

Distance Reg NEC-4 (dB down)

2.5 m 21.2 0.46

5.0 m 42.4 1.5

7.5 m 63.9 4.3

10 m 83.3 14.8

These numbers are so far apart, it looks like I did something terribly wrong. Someone please correct me.
Keep in mind these are preliminary attempts to analyze the NEC-4 based graph that Frank sent me. I really do hope I did something wrong.

Reg'

With the above parameters; summarizing the data obtained so far:

Efficiency 31.8%;
Antenna input resistance component 36.21 - j 3.1, and;
The resonant frequency 8.07 MHz.

73,

Frank

Actually, the question is whether or not one can hear the resulting
noise.

> The size of the charge Vs the dielectric determines how
> much of the charge actually reaches the conductor.

Perhaps you mean the amount of charge Vs. the dielectric determine the
voltage.

> When
> I went from bare wire to 600v insulation, my precipitation

I see your point. The poorer the dielectric and the greater it's
thickness, the lower the induced voltage. There should be some
effect, yes. What'd you use, 20 meters of CRT anode wire or spark
plug wire? :-) The point with which Tom seemed to take issue was the
implication that an antenna with low DC resistance would have lower
precipitation static noise. I also disagree with that notion.

> The worst case of precipitation static seems to be for
> airplane antennas. Insulation is the recommended cure
> although folding is also mentioned. Please do a web
> search for "precipitation static" and see for yourself.
>
> http://www.atis.org/tg2k/_precipitation_static.html

I'm glad we agree on the definitions. In one of your previous
references I noted the term precipitation static used (incorrectly) to
describe the noise associated with static discharge. This is a
distinction I attempted to point out in my earlier post.
Precipitation, among other things, can cause charge to accumulate on

objects which are insulated from ground. This accumulation can continue to increase until breakdown occurs, causing a spark and a noise which is big enough to knock down the receiver AGC for a few seconds (or worse). Precipitation static is the noise which is apparent when a relatively high flux of ions impinges upon an antenna. Low DC impedance antennas won't accumulate large amounts of charge or generate a static discharge, but they are nevertheless sensitive to the static noise just as any other antenna would be. In other words, you and Tom W8JI are both right - you just don't know why. ;-)

Did you see the article in Harper's magazine on W6AM? Pretty neat. Even that article mentioned precipitation static.

Im a new ham setting up a tower in my backyard. Eventually, when I can afford it, I will buy a rotor and a directional antenna. I wanted to run the rotor cable while I have the PVC above ground, and im not sure what kind of cable I would need. Would any 8 conducter cable work? cat cable? telephone cable size okay? I dont want to get something too cheap, but im running 300 ft.

1120. Re: Length & number of radials again

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-24 17:47:51 UTC
From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <hNmdnSrwqLR8lVjZRVnyrA@bt.com>
Source record: 55706

Frank,

Having used NEC4 to derive the input impedance of a single radial, it is now in your hands to settle the discussion about attenuation along radials and the distance at which a radial becomes ineffective. The spectators are waiting!

We already have the input impedance of a single radial of length 10 metres at 7.0 MHz, with resistivity = 150 and permittivity = 16.

Using our standard set of data, I suggest you increase the SINGLE radial length in increments of 3 metres until the input impedance Zin stops changing and becomes relatively constant. That value of Zin will be equal to Zo = Ro + jXo, the complex characteristic impedance of the equivalent transmission line.

It might never become absolutely constant because NEC4 will take into acount the effect of current flowing in the soil which, although it is decreasing, eventually it will be substantially greater than that in a long radial. (My program does not do this.) But you should be able to judge the distance at which radial attenuation is about 18 or 20dB, ie., when Zin = Zo.

The question of efficiency is of less importance. It doesn't matter what the efficiency is because you are using the antenna input impedance plus radial input impedance only to deduce radial input impedance in the same way as if you were measuring it. Be careful with the signs of reactances. ;o)

At your leisure you may find a way how to do 36 and other numbers of radials, at different frequencies. A 1/4-wave resonant antenna is always best. The optimum length of a radial will decrease as frequency increases. At 14 MHz the effect of permittivity kicks in quite strongly. And with 120 or more radials you might be able to demonstrate BL&E were quite correct when they concluded that a virtually perfect ground. at MF, is independent of soil conditions.

Reg.

1121. Re: Length & number of radials again

Source record: 55707

Corrected numbers for linearly segemented radials from Frank's latest NEC-4 model of one buried radial wire, compared to Reg's program.

> Side by side with the NEC-4 data
>

This is how many dB down the current is as you move outward from the origin of the radial.

Distance Reg NEC-4 (dB down)

1.0 m 2.5 1.3

3.5 m 8.7 4.4

5.9 m 14.9 8.7

8.5 m 21.4 10.0

9.7 m 24.4 23.8

Conclusion: the current drop along the radial is no where near as fast as Radials3 predicts, therefore shortening the radials as much as the program shows will increase losses significantly.

I find it VERY interesting, that at the full length of 10m, there is good agreement between Reg's program and NEC-4.

If I were going to base my conclusions on this preliminary small sample, I would say that Reg's program does not hold up for short radials. BL&E, W8JI and now NEC-4 all indicate that there is no where near 20 dB of attenuation in short radials. To confirm this isn't an odd case, a lot more runs would need to be done with varying lengths and radial numbers...but I have to say, it ain't lookin' good for Radials3 in terms of fairly representing the rapidity with which currents diminish on a radial wire over its length.

Bottom Line:

For the present, the articles in QST, ARRL Handbook, Low-Band DX'ing and W8JI's findings are the ones I would follow. The first three are all the same study and that formula is based on BL&E. The following data are from a spreadsheet I used to calculate the optimum length and number of radials based on the above sources. I put the BL&E data in the spreadsheet as a reference. The numbers are how many dB down the field strength was for a given number and length of radials.

Brn/Lw/Ep

Rad 0.137 wl 0.274 wl 0.411 wl
2 -4.36 -4.36 -4.05
15 -2.40 -1.93 -1.65
30 -2.40 -1.44 -0.97
60 -2.00 -0.66 -0.42
113 -2.00 -0.51 0 (Ref)

Here are a few runs for 80 meters of various numbers and lengths of radials that should be within a dB or so of optimum (BL&E).(Based on the references noted above) 3.7 mhz, 1/4 wave vertical. The formula is based on tip separation at the perimeter. Too much separation increases loss, too little wastes wire. All based on wavelenthgs, of course. I believe the maximum tip separation recommended was .015 wavelength.

Available Wire # of Radials Length of Radials
500' 25 19.7' (not within a dB, not
enough wire)
1000' 36 27.8' (not within a dB, not
enough wire)
1500' 44 34.0'
2000' 51 39.3'
3116' 63 49.0 (should be within 0.5 dB
of BL&E Optimum)

My final setup will be 46 radials 50' long. I have 26 right now. It looks like for 50' long radials, I should really have 63 of them, otherwise, I could have stayed at 51 radials only 39.3' long. All this says is that I'm not making the "most" out of the available wire I had. (which makes sense, given I've added radials over time, and didn't have a final plan).

At this point, it looks like when copper prices drop, I need to get another 850' of wire and put in 17 more radials and I will have met the criteria for the formula. (Be within 0.5 dB of maximum field strength according to BL*E).

If anyone wants a copy of the Excel spreadsheet, just email me and I'll send it to you as an attachment.
Only two variables should be entered: Total length of available wire and Frequency in Mhz. Everything else is calcuated.(I did not protect any of the fields, so if you enter data into a calculated field, you'll have to reload your spreadsheet from a non-messed-up one...so save a virgin copy somewhere until you protect the appropriate cells.)

For a typical Ham-IV rotator, total resistance for Terminals 1 & 2
should be 0.8 ohms
and 2.0 ohms for the other 6. Hy-Gain's manual says:

http://www.hy-gain.com/man/pdf/HAM-IV.pdf (page 4)

Maximum Gauge for Gauge for
Length Terminals 1 & 2 Terminals 3-8

300' (91 m) #14 (1.75 mm) #16 (1.42 mm)

You can mount the motor capacitor at the rotator instead of inside the
control box and eliminate the need for two #16 wires (terminals 3 and
4). In this case you could parallel two of the smaller wires with the
two larger wires for Terminals 1 & 2.

A 300' run of rotor cable is not cheap! Think $360 ($1.19/ft).

I once used disc ceramic bypass caps to try to tune an
antenna. They went up in flames. For a small loop, I
would at least use doorknob quality caps.

size = amount = magnitude = amplitude. It is hard to visualize
how a charge could make it to the conductor without the migration
of a quantum particle.

> The point with which Tom seemed to take issue was the implication
> that an antenna with low DC resistance would have lower precipitation
> static noise. I also disagree with that notion.

Both of you misunderstood the definition of "noise" that I was
using. With the feedline completely disconnected from the
transceiver, arcing occurred and that aural noise woke me up at
night. It was aural noise from the arcing caused by precipitation
static charge tansfer that woke me up and a low DC resistance
eliminated it.

> just don't know why. ;-)

When a charge hits a closed loop, there are two paths it can take
to equalize the charge around the loop. Only one of those paths
is through the receiver and that is a higher impedance path than
the other path. When a single-wire dipole needs to equalize the
charges between the dipole elements, there is only one path available
- through the receiver which often has a capacitor in series and thus
blocks DC charge equalization. This is, of course, not the only reason
that a loop is quieter than a single-wire dipole but is simply one of
the reasons.

Incidentally, "Quietflex" antenna wire, with its 1000v insulation
reduced the problem to an acceptable level in the Arizona desert.
I still use that wire for my dipoles.

Fellow Experimenters, Frank and Hasan.

I havn't the foggiest idea what you are doing with NEC4 but you should be aware that, according to Radial_3, there are 3 resonant frequencies with a single radial at lengths shorter than 10 metres and at a frequency of 7 MHz.

The propagation velocity is very low. VF = 0.225

Funny unexpected things happen on multi-resonant lines especially when Zo has a relatively large positive angle. Before you draw any conclusions about deducing attenuation from your output data you should take into account the line is -

1/4-wave resonant at 2.4 metres.
1/2-wave resonant at 4.8 metres.
3/4-wave resonant at 7.4 metres.

and at 10 metres it is very near to full-wave resonance. It can be assumed the far end is open-circuit. Actually it isn't. It behaves as if it is slightly longer.

It is significant that at 10 metres and 7 MHz, you have concluded that the radial is about 20dB long. Which approximately agrees with my program as being the length beyond which there is not much point in extending it.

But the best way of determining attenuation is to do what I have suggested - increase radial length in short increments and observe what happens to radial input impedance. Eventually, Zin will converge on Zo if it hasn't already done so. I should very much like to know what Zo is and at what length it occurs. I have to assume NEC4 knows what it's doing! ;o)

Cec,

I don't have enough time left to write a thick book. But as an engineer and radio amateur with 60 years (on and off) experience of transmission lines (from 0.05 Hz to 3 GHz), and having once read something about Oliver Heaviside's trouble with university professors, I was able to make an intelligent guess.

It remains to be seen what the uncertainty is.

Isn't there anything in the Handbook or Google? ;o)

Yours, Reg.

Hmmmm... 300 feet!
There'll be voltage drops.

Do you already know the rotator you'll be using? "Would any 8 conducter
cable work?" makes it sound so.

My current rotator use a 5-wire set-up. The one before that was a
6-wire lash-up. What I've always used is loss-leader, 100' 14 ga.
extension cords. You'll see these from time-to-time at a Real Good
price at the chain and/or Big Box hardware stores. Since I've never
needed more than about 70-80 feet, they serve me well. (And, if I cut
Just Right, I can make up some 8-10-12 foot extension cords and/or
replacement cords for power tools.) For the 5-wire configuration, I
parallel the 2 ground ("green") wires of the two cords to serve as the
common return for the motor windings and the position pot.

I don't know where you're located, but eliminating the voltage drop will
be a Big Plus when you want to swing your collectionairy at midnight on
a cold Winter's night. I used to live in Gunnison, Colorado and getting
that sucker to wave around at 20-25 below zero after the sun went down
was always dicey.

You need rotor cable. The Belden 9405 has 8 wires: 2 x #16 and 6 x #18.
Sells for 94 cents a foot at AES. Probably cheaper elsewhere. You would
probably be best off with a Yaesu rotator for these reasons:

1) About 1/3 cheaper up front.

2) Uses a DC motor. These won't stall at low voltage, just run slower.

3) Require 6 wires, instead of 8. Only 5 of the 6 are actually used. What I
did was to use 8 conductor cable, and connect 2 wires in parallel for the 2
motor wires.

What you should do for any rotor installation is to first connect the
control box to the rotator on the kitchen table, or wherever, using the
actual whole piece of cable you plan to use.

Reg, Note that I am making all my calculations at 8.07 MHz, where
the structure is very close to resonance. NEC does indicate
the resonant lengths of the radials as follows:

1/4 wave = 2 m;
1/2 wave = 4 m......etc., to 1.25 wavelengths at 10 m.

I will try your suggestion of gradually increasing radial length
until I see a convergence trend at the complex Zo.

We have to keep trying to save Ham radio while we still can because once it's all the way in the shitter it will be even harder to pull back out & clean up.

A Ham who'll stand for nothing will sit for anything. I won't accept more dumbing down.

Help save Ham radio:

1- No more automatic renewals. Individuals must retest and pass all elements required for their license class every ten years.

2- The passing score for written exams needs to be raised to 85%.

3- Code elements should be 13 wpm for General, and 20 wpm for Extra.

4- Make the no-code license one year non-renewable.

5- Cancel your ARRL membership until they decide to work to improve things and stop them from proposing ham radio that is like CB.

was possible to mix up my answer sheet with someon elses SC but that
would not have affected me passing every one passed the day I took
mine
I passed to 2 elemt test for tech we used ot have and I have passed the
the general and extra class written waiting for the plug to be plulled
on code testing

Look like for time on the CSSE I moay need to retake the general
element but that isn't rough

From the NEC-2 User's Guide, p. 11: ". . .for a horizontal wire with radius a, and height h, to the wire axis, [h^2 + a^2]^1/2 should be greater than about 10^-6 wavelenths. Furthermore, the height should be at least several times the radius for the thin-wire approximation to be valid." All I can find in the NEC-4 manual is the restriction in terms of wire radius.

Frank,

After correcting the resonant lengths for the change in frequency from 7 to 8.07 MHz there is almost exact agreement between NEC4 and Radial_3.

Keep a record of length, Rin, jXin for each incremental increase in length. They could be useful.

When using Radial_3 set the number of radials to 1. The input impedance of the radial system will then be same as the input to the single radial and will be displayed with a greater number of significant figures.

When you compare results between the two programs set the frequency on Radial_3 also to 8.07 MHz. The resonant frequency of the Radial_3 antenna is slightly higher - it's something to do with the end-effect and the fact that a vertical antenna needs pruning by a few percent to make it resonate at the theoretical value of 75/Height MHz. Since at present we are concerned only with the radials it is better to use the same frequency for both programs.

I think that will complete all I have in mind. It may involve you with a tedious amount of work. If you find it interesting you could do something similar at 28 MHz. The 20dB limit may be reached with an even shorter length of radial. Radial resonances (which BL&E never dreamed of) will be much more pronounced especially with high ground resistivity.

Has anybody ever generated an input table for 120 radials?

It's all in the cause of Science. Thanking you in advance.

Reg.

(snip)

Does Radial_3 assume that each radial is independent of its neighbors,
regardless of how close or far?

Thanks Roy, To be honest I did not really check the NEC 2 manual,
just NEC 4, so understand why I could not find it. My NEC 2
manual is probably a different version -- WDBN version 0.92,
and it appears on page 13.

Regards,

Frank

I find this very interesting Reg, and learn more about NEC
all the time. I think I could probably do a 120 radial model;
particularly with segment length tapering. With linear
segmentation, and 0.025 m segment length, the 36 radial
model has almost 15,000 segments. It seems that
radial segments can be sloped to their final depth, so
can probably reduce the segmentation requirement.

Reg,

I have no idea what BL&E might have dreamed of, but I did find one
curious item on the fifth page of their paper (page 757 in the original).

<<<<<

Where there are radial ground wires present, the earth current consists
of two components, part of which flows in the earth itself and the
remainder of which flows in the buried wires. As the current flows in
toward the antenna, it is continually added to by more displacement
currents flowing into the earth. It is not necessarily true that the
earth currents will increase because of this additional displacement
current, since all the various components differ in phase.

>>>>>

Whether this is "resonance" I cannot say. However, it is pretty clear
they understood that the radial currents did not monotonically increase
as the distance from the antenna decreased. There was some sort of
variation.

Their figure 42 seems to show significant "resonance", but there does
not appear to be any discussion of that behavior.

73,
Gene

I would also look for RF caps with a KVAR ratings.

Most caps even doorknobs are just simple HV power supply doorknobs with
no RF ratings. Ebay is full of this stuff, most of them are useless at HF.

Many of these caps have a resonance dip in them. I have found many that
dip at 7,8 and 13mhz. When i applied power you can figure out what
happened! So check them with a dipper. Good caps like HT57s will have
no dips. Some of the Russian pancake types are also good, but most are
GP high voltage caps for laser power supplies.

The ultimate caps are Tubular Types made by people like Morgan, however
they would make wire antenna with caps as expensive as a Steppir!
I was lucky enough to find a few of these for cheap and used them on a
N6LF type improved zepp antenna. These caps were rated at 50 KVar.
Someone told me 1kvar is about a kilowatt.

Thanks to all for replies,
Actually my requirement is to pump 4W into 1meter diameter loop
antenna.
I need to tune the antenna to resonance 13.56Mhz and then match it.
I using some fixed capacitors and variable capacitors of small range
for fine tuning.
Now i am using ceramic fixed and ceramic variable capacitors and found
that its performance is good (I am not sure, the problem may in my
transceiver also).

I thinking of trying other capacitors, how about following combinations
mica fixed + mica variable
mica fixed + air variable

Is it worth to buy mica capacitors ?
can i simply buy mica capacitors ? , i found some vendors selling rf
mica capacitors ,
is there any big difference between them for HF frequency ?

regards,
palani

You're most likely correct on getting into the "politics" of the ARRL to "try" to get anywhere. But, good luck. It is more like a "good ole boys club". Anytime I've ever seen any reps to the area at a hamfest - they acted like snobs more than trying to communicate with hams of their concerns OR to try to win those hams who weren't members - to become members. If the rep couldn't give me the time of day, the ARRL didn't need my money either. I stopped my membership when it was due for renewal. That was a good 15 years ago or better. How did the rep act like a snob? He turned to his bud who was with him behind the table and ignored others "trying" to gain his attention and talk to him about whatever. Oh - he may look and say Hi, but god forbid you interrupt his conversation with his buddy. So much for the "MEET YOUR ARRL REP HERE"

lou

The sign reads, "Instant Gratification". Buy the equipment and be
able to put it on the air immediately.

It wouldn't surprise me if, in the not too distant future, one will be
able to buy a ham transceiver, create call letters out of one's
initials or something and legally be on the air while waiting for the
real "ask for it and you get it for a fee" license.

Another option is to homebrew your own capacitors. I've seen descriptions of magloop-antenna tuning caps of a number of interesting sorts which are fairly easy to homebrew:

- A sheet of glass as the dielectric, with metal plates (or the surface copper of sheets of PC-board material) as the electrodes. These can be made variable by arranging to slide one plate-electrode over, or away from, the other.

- Fixed caps made of PC-board material (etch away a strip around the edge of each side to prevent arcing)

- "trombone" caps made of concentric copper or brass pipe or tubing, with Teflon or polyethylene film rolled onto the inner tubing as a dielectric.

If you only require single-frequency operation you might be able to build a metal-and-glass or PC-board fixed cap which has more capacity than you need, and them trim it (literally) by removing a bit of the metal at a time until you reduce the capacity to the value which establishes resonance at your operating frequency.

Why? I assume you really mean that the current crop of new hams needs education. Have you done anything? How many new hams have you elmered?

Are you active on 2m? Do you speak to new no-code hams and offer to teach them morse code, let them see your HF station in operation? Have them assist you during contests?

If all you do is hang out on the HF bands, and complain about how bad the new hams are, they will stay that way. Whose fault is that?

73,

Geoff.

I find it easier to think in terms of ground currents flowing 'away' from the focal point rather than coming into it.

At 3 MHz, where BL&E made their measurements, in ordinary soils there are hardly enough resonant effects to be noticed. At MF and below there are no resonant effects. The equivalent transmission line is mainly resistive. There is inductance of the radial wire but propagation is largely independent of the value of soil permittivity and hence on 'capacitance'.

Resonance effects begin to show at 7 MHz, At 21 MHz permittivity and inductance predominate - especially with high ground resistivities.

At higher frequencies in very high resistance soils, buried radials take on the characteristics of the elevated variety. But nobody uses buried radials with vertical antennas at 30 MHz and above. Everybody switches to dipoles!

=====================================

No John. The input impedance of a set of radials is not the sum of
the individuals all in parallel. Input impedance is a non-linear
function of N, the number of radials.

Reg.

Cecil, could you or somebody, please use Eznec or something, to determine the radiating efficiency of a 9.0 meter long vertical antenna with a ground-loss connection resistance of 5 ohms, at its 1/4-wave resonant frequency slightly above 8 MHz.

Will discuss the result later.

- and oblige Reg.

Source record: 55756

Cecil,

There has been a temporary improvement in my Alzeimer's affliction.

The attenuation along a radial is given by =

Attenuation = (R / Ro + G * Ro) / 2 nepers.

Where -

R = HF Conductor resistance.
G = Shunt leakance or conductance, related to soil conductivity.
Ro = Resistive component of line impedance Zo.

One neper = 8.686 dB.

If I published the source code you would be asking even more questions
and Richard Clark would again unjustly accuse me of trolling. ;o)

Reg.

1170. Re: Is It double bazooka less noisy?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-25 11:58:24 UTC
From: w8ji@akorn.net
Message-ID: <1153828704.177146.42840@m73g2000cwd.googlegroups.com>
Source record: 55757

For the past few days we had rain and lighting. Prior to any rain hitting my antennas the steeady background noise hissing came up.

The noise came up first on my high dipoles, two regular dipoles at 150-160 feet. One was bare #14 copperweld, the other is insulated #10. they were both equal as near as I could tell.

It came up the same but later in time on my three low 80 meter dipole antennas at about the same rate. Two were bare wire and one was a coaxial double bazooka. All are at about 35-40 feet high.

I have a 1/4 wl shorted stub I use as a second harmonic trap on 80 meters. It switches in and out with a relay on an RCS-8V switch that selects trunk lines to antennas. I pulled the relay wire off, and the 80 meter dipoles had then same steady noise as with the stub in. The dc path had no effect at all on steady noise, but on the high dipoles, both the insulated one and bare one, there was a popping noise about once every second or two that went away with the dipoles center conductor grounded. I could hear this popping noise on any antenna near the dipoles.

I added a 470K resistor to the 80M feedlines and the popping noise quit. I removed it and added a choke and the popping noise quit. When lightning would hit the popping noise would quit for a while, and then come back.

As the storm got worse the noise got worse. When the rain was very heavy and lightning very close, I stopped for a while. At that point the noise was terrible on all antennas, but definately worse in level on the high antennas. It was no better and no worse on any antenna at the same height.

All through this my IAC double bazooka was no quieter than a regular dipole made from #16 bare copper located 100 feet away at the same height.

This test was with all antennas in place at the same time on the same day in the same weather.

73 Tom

Personally, I would rather have the First Class and Second Class Radio Telephone back. Thank the broadcasters for lobbying to eliminate that requirement -- ironic that the industry has been sliding ever since (go figure) --
and of course -- this happen at the same time that personal computers for business usage were expanding, LAN for the PCs & cellular telephones introduced, and AT&T was broken up (1984 Judge Green order). SO -- the best "talent" left the industry (since the industry no longer wanted to pay for it).

I think he said 4 watts to a one meter loop. Even in that
application, I suspect the physical flexing of ceramic caps
would cause losses. After mine caught on fire, I found out
that at least some ceramic caps are designed to be biased by DC.

Is the 5 ohms of ground loss the only loss in the system?
i.e. should perfect ground be used? Or should it be done
in free space with a 5 ohm load going to the radials.

Will integrating the area of the omnidirectional elevation
envelope yield a value proportional to the radiated power?

I should have said a rule of thumb. A 1kvar capacitor should be good for a kilowatt amplifier. I believe KVAR, RF current and RF voltage to be a complex matter. Maybe someone really smart could write a program that could work out what the TRUE RF current rating of a capacitor is versus frequency and its KVAR rating, now that would be useful.

> day in the same weather.

Precipitation static doesn't always occur during thunderstorms.
It's effects are greatly reduced in high humidity environments.
For precipitation static to occur requires charged particles.
And you don't know if charged particles even existed during
your experiment. To separate charged particle effects from
lightning effects you need to run your experiment without
the clouds and thunderstorms under conditions that guarantee
charged particles. That would be during a dust storm on a clear
sky day under low humidity conditions as often exist in Queen
Creek, AZ.

Precipitation static is a large problem for airplanes but
only when they are flying through a field of charged particles.
One of the treatments for precipitation static on airplane
antennas is to insulate the antenna inside a non-conductive
pipe. Another treatment is to fold the antenna. These are
well known, well accepted methods of reducing precipitation
static problems on airplane antennas. You can verify those
facts for yourself through a little web research.

>couple feet of its quarter wave ground plane antenna.
>
>
>Is there a certain cable length I should use to tune for maximum gain?

There are some very common misconceptions around regarding
cable length impedance matching.

Ideally your antenna has 50 ohms, the cable has 50 ohms,
the transmitter has 50 and there is perfect matching all the time,
at any cable length.

Side note:
Did you note I left out the receiver?
Does anybody know the input impedance of his receivers in use?
How would you measure the input impedance?

Back to the cable lenght, may I spill a few words.
One may use the feed cable to match a non 50 Ohm antenna
to the 50 ohm transmitter, but that works sufficiently only for
a very narrow frequency range. Some people do it on shortwave
and they switch different lenght cable loops with a relais
to cover an entire SW band. Works fine, if no antenna tuner
is available. On the UKW bands this is rather unusual,
and normally not necessary. Go and tweak the antenna
lenght and the radials to optimum SWR. The cable tuning
method may fail with broadband antennas, of course.

Cecil,

This is close to being an all-time RRAA classic.

Precipitation, at least in the form of rain, often occurs when the
humidity is quite high.

Do you suppose they should have named it dust storm static rather than
precipitation static? Or perhaps dry rain static?

Cecil, that is what I did with NEC, and got an efficiency
of about 35%. Using the ratio of Rr/(Rr+Rloss)
produces a totally different answer.

NEC 4 computes a normalized far field, at 1 m, in units
of volts. NEC 2 incorrectly shows units of V/m.

Pat,
Thanks for the input.
I have a question.

Why do you say that the antenna was meant to be fed using open wire
feedline?

In the article, it shows an SO239 bulkhead to be attached to RG8U cable.

Yes, and triboelectric charging is known to be magnitudes
worse in low humidity conditions. On this web page:

http://www.esda.org/basics/part1.cfm

it says that a worker at a bench can expect 6000v when the
relative humidity is 10-25% Vs 100v when the relative humidity
is 65-90%.

> Do you suppose they should have named it dust storm static rather than
> precipitation static? Or perhaps dry rain static?

"Charged particle" static would have been more descriptive
since "precipitation" is most associated with falling H2O.

If the relative humidity is 10% when the rain starts falling,
seems the precipitation static would be worse than if the
relative humidity was 90% when the rain started falling.

Dry snow falling in low relative humidity conditions could
certainly carry large charges. Dry wind driven dust particles
in low relative humidity conditions are often associated with
precipitation static.

But assuming that raindrops falling in high humidity conditions
are electrically charged is a questionable assumption. And trying
to detect precipitation static noise in the presence of lightning
seems like looking for a needle in a haystack.

It is good engineering practice to try to isolate what one is
trying to measure. The best way I know of to isolate precipitation
static from other noise sources is to perform the measurements
under clear sky, windy, low humidity conditions in the desert.

I strongly suspect that w8ji didn't detect any of the arcing
noise in the double bazooka that he detected in the bare wire
ungrounded dipoles. Was that a noise reduction?

W7EL tells us that EZNEC doesn't display the surface
wave which obviously contains power. Would that affect
the efficiency using the integration technique?

I Hope we talking about the same antenna?

I am talking about the antenna in this months QST page 38 ZS6AAA

"The Compact Quad Multiband Hf Antenna" August 2006

So i hope i have not crossed wires here. But this antenna is open wire
fed, supported on a single fibreglass pole.

Try a short length of RG-8 or similar. Cut it longer than necessary
and then prune it to length.

Hi Reg,

I believe your temporary Alzhiemers affliction began some time ago, when you repeatedly reminded me that BLE forgot to indicate the ground conditions. Even though the conditions are irrelevant when sufficient radials effect a near-perfect ground, you either skimmed BLE too quickly, or the Alzhiemers effect had already taken place. I'm going to quote from two BLE pages below:

"Fig 7 earth conductivity = 0.2 x 10^-4 mhos/cm^3
Fig 8 earth conductivity = 1.0 x 10^-4 mhos/cm^3
Fig 9 earth conductivity = 0.2 x 10^-4 mhos/cm^3
Fig 10 earth conductivity =1.0 x 10^-4 mhos/cm^3"

"Fig 18 shows the distribution of earth loss for G = 22 degrees, and G = 88 degrees, for 15 and 113 radial wires, when the frequency was 3000 kilocycles and the earth conductivity is 0.2 x 10^-4 mhos per cm^3."

It's true they didn't mention permittivity, but at least they did recognize conductivity, and reported it.

On the other hand, concerning the difference in results between using BLE or Radials3, unless I missed the critical point somewhere along the way, perhaps

the difference has been misunderstood, where Radials 3 shows usefulness drops off more quickly with distance from the radiator than BLE. As I understand it, when only a few radials are present, the longer length is unnecessary. I now quote again from BLE:

"Fig. 6 shows the actual current in the earth for the same conditions. These diagrams show that the ground system consisting of only 15 radial wires need not be more than 0.1 wavelength long, while the system consisting of 113 radials is still effective out to 0.5 wavelength."

Does this not agree with Reg's Radials3? If not, please tell me what I'm missing. (I do not have Radials3, and am only commenting from what I've read in the various posts.)

In 1964 I passed the 13 WPM test on the first try at the Dallas FCC office.
I was 14. There are plenty who can top that, I'm sure.

The rulemakers "stabbed themselves in the back with their own ballpoints"
(To quote an article from Electronics World in 1962.) when they created CB.
But, as said article went on to point out, the industry needed a shot in the
arm. That article has stuck in my head to this day.

This isn't about creating the best operators, it's about selling the most
junk and having the most votes.

Buy 300 feet of regular cable. The kind made for 100 foot runs. Do a quick check on the kitchen table. Measure the voltage at the motor, note the voltage drop in the cable.
Rig up a transformer in series with the line to the rotor such that it kicks up the voltage. I did this successfully a while back. Yes it takes a little effort but works perfectly. As I remember I kicked up the 24 volts on a CDE rotor to about 30.
The other wires in the cable are used for detecting the position of the rotor and can tolerate the long run.
The other thing you can do if you have enough scrap romex or other copper wire is to parallel it with the rotor cable. Not necessary to have enough to go the entire 300 feet. For example, if you have enough of say #12 romex cable to go from the shack to the base of the tower, use it to parrallel the rotor cable and make your measurements. Use your head, experiment. It is just ohms law we are dealing with here, not rocket science. Good luck.

<...._.--_.-_-..._-._.._--.@.-_---_-._*_.-_-> wrote:

>Does anybody know the input impedance of his receivers in use?

Hi Helmut,

Stand-alone receivers may differ, but in transceivers, the receive path, up to a point, is identical to the transmit path. As such, a 50 Ohm design is universal. Now, if there is any divergence from that value, you must expect that signal power is being reflected away from the detector. Certainly, any high Z active amplifier may be used, but in an untuned front end, this is hardly a virtue.

Stand-alone receivers, like the R-390, can have higher Z inputs with tuned front ends. The R-390 includes what is called an antenna trimmer to further optimize the input. It also has two distinct antenna inputs, balanced and unbalanced.

>How would you measure the input impedance?

This takes a special signal generator with a known output Z. You simply place a series variable resistor in line, and watch the receiver's signal meter as you vary the resistance until half the voltage is observed. The input Z is the sum of the signal generator's output Z and the variable resistor's value. Take warning that a variable resistor's value is going to be the next difficult thing to determine. It is not simply a matter of measuring its value (or rotational angle) with a VOM. However, absolute accuracy is rarely needed in this regard and a VOM reading will be suitably close.

Hi Walt,

Reggie's only defense against plagiarism (a charge he loves to bandy about) is claiming to have NOT read BLE. It mimics his railing against software users as intellectual cripples when he has a trove of software offered like dope to school children on the playground.

Reggie,

It is amazing how you can spit in the faces of those commending you for your software; and you do it with full vigor and glee. You may want to ponder your legacy as a maker of crutches (un-referenced executables) or leaving a testimony in open source code. Even with these positive examples you sneer at your source to gain the rhetorical advantage, and yes, that makes you a troll (and this is decidedly different from what the Brit's call eccentrics, or what we call characters).

The one complaint I've heard frequently from you when you are asked to write something comprehensive (there are models in history from Heavysides that you similarly dismiss) is that there is not enough time. You seem to have plenty enough time to anticipate my banter, or to otherwise respond to/with trivialities. This has got to be the height of decadence.

1216. Open-Sleeve Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-25 18:35:49 UTC
From: jawod <jawod@fuse.net>
Message-ID: <bc1c5$44c664d5$453d9423$20294@FUSE.NET>
Source record: 55603

I came across this in the ARRL Antenna Book (p. 7-21) 20th Edition.

For such a simple set-up, why haven't I heard of anyone using it?

I understand some commercial verticals use this design in some way.

From what I have read, the open-sleeve design has a simple lambda/4
vertical with two side vertical elements of given d diameter and
distance D from the center vertical (monopole).

Given the improvement of SWR bandwidth shown, why isn't this a more
popular approach? (or is it, and I just don't know it?)

:-)

Bill, I had a master machinist work for me in the 1960s. He could make ANYTHING!!

I asked him if he could make a car. Sure!! His reply: "All I need is a block of steel 6X6X20 feet, a large milling machine, and a large lathe."

He was a Ham Radio Operator, Collins stuff of the 60s.

why try again?
that is what is insited on by the CW advocates along with anybody that
opposes the requirement is lazy or wnat to turn the ARS into CB no
proof no evidence just mantras

Id rather answer what does a CW test show about my abilty to operate on
HF when I have no intention to ever use CW. I d love an answer to that
question but I will nver get it either

> much nicer than "the manufacturers need more money".

Listen!

"THE MANUFACTURERS NEED MORE MONEY."

"THE MANUFACTURERS NEED BIGGER MARKETS."

"THE MANUFACTURERS NEED MORE ..."

Design and manufacture of any electronics item requires a market to recover design costs, to recover manufacturing tooling costs, to cover distribution costs, to provide a return on investment, to provide a return on equity, to provide net profits to cover medical insurance, to provide net profits for stock retirement plans, to feed the engine of the economy.

The cost of a single DSP chip that operates at high i.f. frequencies has to be recovered or the chip designer goes BANKRUPT. How many radios must be sold to recover a million dollar investment in a single chip?

"THE MANUFACTURERS NEED BIGGER MARKETS."

Follow the money. Understand our hobby/public service!

Finally then, the question becomes not whether we are appliance operators [most of us are], but do we wish to advance the radio art? "How do we advance the radio art?" is a complex question with many answers.

Is preserving historic skills part of the art? Is operating AM, when most HF is SSB, part of the art? Is ragchewing part of the art? Is EME part of the art? Is old fashioned RTTY part of the art? Is current digital communication part of the art [most of today's digital is actually ancient]? I say NO!

But, taking the time, using the energy to learn, investing our money in technology and learning that technology is contributing to the art. Or, is it?

As usual, reading manuals would really help. It seems that
I4, a four digit integer, in the RP card, can provide the
necessary information. With a 9 m monopole, and 36
10 m radials, 25 mm below ground. All wires #14 AWG.
The radiation efficiency is 32% at 8.07 MHz (Antenna resonant
frequency).

1235. Newbie Question: HELP!! Antenna Noise

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-25 20:54:49 UTC
From: Timothy@tholtom.freeserve.co.uk
Message-ID: <1153860889.661316.158250@m73g2000cwd.googlegroups.com>
Source record: 55622

I decided to try one of the simplest of antennas, a quarter wave vertical for 20m supported by a roach pole.

I live on the 9th (top) floor of an appartment block, with a balcony. The balcony is surrounded by a a metal railing which I decided to use as the counterpoise.

I have a portable communications receiver with a small helical antenna. Obviously this gives limited performance with this antenna...

Anyway, hooked up the antenna to 50 Ohm coax and connected the other end to the comms receiver.

Result? Noise at about 8 S units, all but drowmning out the signal. If I remove the counterpoise, it's even worse, a howling sound. If I short the counterpoise and vertical, the signal is actually BETTER. If I go back to the little helical that comes with the comms receiver, then the noise VANISHES and the signal's not bad either!!!

Question: What am I doing wrong? How can I improve the vertical (without moving)?

Question: Are there any other antennas that would be better in this situation (9th floor appartment)? Magnetic Loop?

Any help anyone can give would be MOST welcome!!!!

Tim

Hi Tim,

You give a very good description of your problem. There's more that could be said, but it starts very well.

First, we can start with what is good. You get no noise and a good signal with your little helical. I presume this is a battery operated set, or could be battery operated. If not, connect it to an extension line (but try to go battery operated).

Move your set to the balcony and see if the noise returns. If so, use the set to try and locate the noise. If not, then your problem is between where you are listening and where the new antenna is going to be.

Try tracing that path back while monitoring on your set to see if any noise sources are along the way (this is unlikely, and shielded coax should take care of it). If so, we will discuss this below. If not, then my bet is your noise will be discovered in the next test.

Put your set back into its usual operating area. Connect the coax to the set. Disconnect the coax from both the balcony and the antenna (the far end of the coax is just floating - don't let it touch any metal) and check for noise. If not, you are ready for the next test. If so, the problem may still be related to the next test, but I would bet your coax is connected to something metallic along the way.

Connect JUST the coax shield to the rail of your balcony. If you get noise AND your set is plugged in (try this too, if you normally use it with AC power); then you have a ground loop, or conducted noise. You can retain the "ground" side of the antenna with the rail, if you insert a capacitor between the coax shield and the rail. However, this is a Hail Mary kinda of solution and will not be entirely satisfactory. If you don't get the noise through this one connection and finishing with a connection to the antenna does, then there is one more thing you can do.

At the antenna end, coil the coax with about 8 - 12 turns around a coffee can or large canister or 2 liter pop bottle just before the bitter end where connections are made. If this reduces the noise, that noise is arriving from somewhere along the path and being coupled into the line at the antenna. Alternatively, your set may need grounding too. Problem here is that you are a long way from RF ground (9 floors away), and that need for ground is more a need for shielding around the set. All of this argues local noise, so it serves your interest to find it.

One quick way is to kill power to the entire building and successively add it back until the noise reappears. This, of course, is a fantasy; but you could do it for your own apartment at the breaker panel. If you still have noise in a dead apartment (battery operation of course); then you have problematic neighbors. This still demands that you haul that set around snooping for the source of noise. If the noise went away, sometimes it arrives from a distant source (in the apartment) that SHARES the same breaker (other side of the wall?). If so, experiment with plugging your set into other outlets on different breakers (use an extension line so that you don't have to move the set).

If we have to return to the balcony rail as the culprit, then build two antennas and connect one to the coax shield, one to the coax inner conductor, make the coil described above (or look for a 1:1 current balun), and make SURE that nothing touches the railing, electrically.

Sleeve vertical dipoles are quite common, but I don't get the
description of
two vertical side elements...?? The usual sleeve vertical is a 1/4 wave
radiator, and a 1/4 wave tube, open on the bottom, as the lower half
of the antenna. The better designs use a second 1/4 wave sleeve as
a decoupling section. These antennas are pretty prone to common mode
spillover if you don't use a lower decoupling section. The coax runs
up
the middle of both sleeves. The shield of the coax is connected to the
top
closed end of the lower decoupling sleeve. Open at the bottom, same as

the sleeve above it that is the lower half of the antenna. A company
named
"Dodge" used to make those for many commercial users. IE: police,
etc..
I think it was Dodge anyway.. The design has been around a long time.

Couldn't be. I didn't know what the schematic was for
a double bazooka until I looked it up last week. The
double bazooka uses the same techniques that are used
on airplanes to reduce precipitation static.

Well, here's something new...responding to my own post (sort of)

As I started to collect parts needed for this antenna, I realize that
lightweight aluminum tubing at 7/8, 3/4 and 5/8 inches is not available
from Loews.

What's a good local source for aluminum tubing?

Actually, one doesn't even need two side elements. One
element will function with the outside braid to turn
the decoupling section into a balanced 1/4WL stub which
functions essentially the same as the unbalanced 1/4WL
decoupling sleeve. Such is illustrated on page 26-9,
Fig 11, of my 15th edition of The ARRL Antenna Book.

Source record: 55631

The open sleeve that AB8WH is referencing is several very closely spaced elements of various lengths around a central element that is directly driven by the feedline.

The other elements are very tightly coupled to the driven one because they're so close, and so it's a good construction for broadening SWR bandwidth (several overlapping resonances, elements almost the same length) or making a multi band antenna (several widely spaced resonances, elements widely different lengths)

- - - - - -

I think some HF multiband yagi manufacturers are using them... I don't remember who. Also, many of the wideband long boom VHF yagi designs have a director that ends up very closely spaced to the driven element, essentially an open sleeve...

As to why you don't see more of them? I dunno, there are lots of ways to make a multiband antenna. You could do the same thing out of tubing but do it fan-dipole style and connect them all together. You could use traps and cut out the amount of tubing you need. As far as broadbanding, you typically only need it on the lower bands (80/75m comes to mind) and there you'd be talking the erection of two ~70 foot elements instead of one just to broaden your SWR curve even though running a 3:1 SWR on your line and using the tuner in the rig would add negligble loss. Better to take the other 70 feet of aluminum and space it a half wavelength away from the first and phase them into a broadside/endfire array.

I think the dimensions are a bit critical like a parallel multiband dipole can be... lots of interaction between the elements. I don't think they've got much of a marketing advantage right now, either. Otherwise "open sleeve" would be an oft-heard buzzword in antenna ads something like "linear loaded" or "no lossy traps".

Certainly an antenna construction worth knowing about, though... I thought about building one when I first saw it too. Also, I was playing with the possibility of adding a 2m yagi to my 6m moxon rectangle the driven element of which would be open sleeve coupled. Haven't had much success getting good front to back on 2m in the model though, so I haven't pursued it. That's not the fault of the open sleeveness... I think I need to start with a known good yagi design first.

73,
Dan

If you can't find Aluminum, see if you can get emt conduit in lengths
that will work. (heavy)

Don't use Aluminum. Hams have been building Quads and Deltas for 60
years using bamboo or fibreglass, with the wire taped or ty-wrapped to
the bamboo (fishing pole). You can get the fibreglass from Maxgain if
you want to go that route.

If you are dead set on duplicating the Author, try Texas Towers, they
sell different lengths of Aluminum.

Copper and aluminum Gutters work great!...If they only run across the front and back of the house you can connect them with a small wire across the roof to make for a nice long antenna!

For example I'm hooked to the bottom of a downspout near the ground on my 3 story home....about 28 feet up the guttering starts and runs 25 feet across the back of the house......I connected a wire across the roof (60 feet long) to the end of the front gutter thats the same height and length.

166 feet of antenna in the shape of an upside down U !

I buried a couple of ground radials next to a fence for 160...80....40 and added a few short ones for 20 /15 and 10 about an inch deep in the yard.....works great with a tuner and is fantastic on the L and AM bands for reception as well!

Other than a small 4 inch length of coax behind the house next to the garage door.....Its invisible!

Yah friggen right, NOT! Continuing to stay knowledgable and re-testing won't improve things? Sheesh!! What's your problem then, If licensees remembered what was on their exams ten years ago passing the exams again should be a breeze. Of course, if they don't rememeber, they'll have to study again. This will make better hams. And the fact that this requirement has never existed in the history of ham radio doesn't make it a bad idea. You're just Lazy.

>>
>> 2- The passing score for written exams needs to be raised to 85%.

It DOES make a difference. It maintains the number of ways we can exchange information, and as a filter to keep out some of the riff-raff allowing you better enjoyment of the service.

>>
>> 4- Make the no-code license one year non-renewable.
>>
>
> Probably wouldn't make any difference.

Of course it WILL make a difference! It creates an incentive to keep studying and building on radio knowledge & skill by requiring an upgrade after a year. And we end up with more knowledgable hams. How can that be bad?

>>
>> 5- Cancel your ARRL membership until they decide to work to improve

The ARRL knew what it's members wanted before restructuring through surveys of the membership, then did you read the proposal that came out with? Totally opposite of the feeling of the membership. Google it, we discussed it long and hard years ago when RRAP groupies actually argued policy. The ARRL is only interested in padding the corporate bank account, they don't care about the quality of amateurs getting licensed. Our HF bands can sound like CB if means the ARRL can get more money. The ARRL BOD stapped Hiram Percy Maxim in the back. The ARRL doesn't care if you know anything about radio.

We don't have to leave or complain if we can improve licensing a little.
That's what's happening here. Striving for quality.

BTW: Stay strong and safe over there. I support you. Don't stop the
mission until the job is done because if you stop early, you'll just have
to deal with the problem again later and it may be even harder and uglier
to do next time. I think most American's support Israel, but you could
never tell that by watching are liberal main stream media.

Look in ARRL Antenna Compendium Vol 5. It has a all band 40 to 10 meter parallel fed vertical, while not a open sleeve it can achieve the same objective all bands with no traps. This project is ground mounted. I just wonder what would happen to this all band wonder if raised off the ground? Maybe thats why we see all the Commercial antennas like Hygain and MFJ use all sorts of funny contraptions and transformers on the end of their versions of these antennas.

The Hygain Hytower is a similar concept, however not open sleeve.

Pat

> >> the efficiency using the integration technique?
==========

The surface or ground wave is the most important fraction of total radiated power. The correct radiation pattern of a vertical antenna shows maximum radiation along the ground. Angle of maximum radiation = 0 degrees.

When deducing efficiency, to omit power radiated along the ground from the hemispherical integration will result in serious error.

(Efficiency by NEC4) / (Efficiency by formula) = 0.38

I can imagine other losses in addition to loss in the radials but to have the other losses several times greater is a bit much. Where are these large losses? Are they in the soil surface - the only other candidate?

My very first short wave experience ever was listening to HCJB on a 6 transistor BCB radio when I was 10 years old...I tweaked the tuning cap to get the thing as far as possible out of the broadcast band range and the overload from the rural above-ground telephone lines did the rest. Got me started thinking that there just might be radios in other countries, hi hi.

This thread is getting interesting...

Reg, your point that the resonant radial effects are more pronounced at higher frequencies makes me think that a small experiment might be in order.

A 21MHz or so ground mounted monopole with a small radial field would be a minimal investment in materials to do a BLE style empirical investigation, at least compared to that at 3MHz. It wouldn't be a minimal investment in time but might be an interesting experiment.

Given that it would be an epic challenge to measure field strength at a grid of points on a hemisphere surrounding the monopole, I imagine a single point field strength measurement would be an acceptable metric? Thoughts on doing the measurement? I guess BLE would be a good guide for the empiricist.

Not hardly. Every time they change the pool, I get an up-to-date study guide just to keep current and see what's new. Could pass the test any day of the week and twice on Sunday. By the way the exam has changed in 10 years. There is some common stuff but there is also new stuff.

However, the biggest problem would be manpower for conducting the tests. Based on the current number of hams, that would be over 60,000 people retesting every year. The existing test system (and the prior systems when things were administered by the FCC) were all designed around the single testing concept. Essentially, it would mean almost every VE team would need to conduct test sessions weekly or hold huge test sessions monthly. There just aren't enough of us to do that. Plus many facilities now charge for the use of the facility. And the bigger the room, the higher the fee.

I believe in keeping a basic test simply because a person can't determine if they will like code until they've tried it. Plus it is one of the basics of radio. If they have the basics and have thus learned it is not a big, scary hurdle, they will be willing to pursue it in the future since they already know it at a basic level.

The filter argument, I consider totally bogus.

Code is either a basic part of ham radio or it is not. That should be the criteria for determining if it should be tested.

In today's climate, it will not be an incentive. Those who want to upgrade don't need the non-renewability clause. The rest will simply let their licenses lapse. Those who would let it lapse aren't on the air enough to contribute anyway.

So why don't you go run for office and promote your platform? Or form your own lobbying group? Complaining here won't get it done. If you want your platform to prevail, the YOU have to do the work to convince people. While the ARRL proposal was not what I wanted, it did indeed reflect some of the things that a significant percentage wanted.

As far as the ARRL padding the corporate bank account, if that is true, then you need to report them to the IRS as non-profit organizations are not allowed to do this.

Most small portable receivers are designed to be used with a small antenna. When you connect a large antenna, they can be overwhelmed by signals which are much stronger than they're designed to handle. These can be far from the frequency you're trying to listen to, but the overloaded receiver front end generates many signals at many frequencies, often where you're trying to listen. I've found that when I connect a typical scanner or HT type receiver to a decent dipole, I need to add about 20 dB attenuation between the antenna and receiver before the receiver-generated spurs drop to a tolerable level.

This might not be your problem, but I think the chances are good that it is.

Congress just passed and the President signed a Federal Law that stops
the CC&R cops from prohibiting flying the American Flag on your
property. This means you can have a flag pole (antenna). :)

Has anyone purchased a recent ICOM 746PRO radio, and had any problems? I would like to buy one soon, but there seemed to be alot of problems in the early models. I was just wondering how the newer models were holding up.

Correct Reg, I had thought the modified RP card
considered ground wave, but it does not. I am working
on a combined integration including the surface wave,
which should provide a more accurate indication of
the overall efficiency. I will also attempt the
analysis of various lengths of radial wires.

As opposed to making a ham license something anyone can get merely by
asking for one - because, like you, they don't have the intelligence
to pass a real test.

>
> Does RF live and ground not exist on the output connector of the
> transceiver?

Begin with a self-contained, battery-powered transmitter. Put a large metal plate on the ground, stand on the plate, and set the radio on the plate. Touch the radio. No burn. Touch the center conductor. Burn. Just like you said.

But now put the radio on top of an insulator, and connect the center conductor of the antenna connector to the metal plate. Touch the center conductor. No burn. Touch the radio. Burn. Whoa -- you got burned from "0V" -- the "cold" side! No fair!

Finally, insulate the radio and disconnect the center conductor from the plate. Hold on to the radio and touch the center conductor. Burn. Hold on to a wire going to the center conductor. No burn. Touch the radio while you're holding the wire. Burn.

You don't prevent a shock by declaring or "regarding" something to be ground or "0V". You do it by connecting it to the same potential as your body. And declaring it to be "live" doesn't cause the burn -- what causes it is that you're touching something that's at a different potential than your body.

You can check the recent reviews on eHam.net.

Also, at the Icom site, they give a lot of ifs/ands/whats in regard to
what they've done to beef up certain circuits that were blowing out,
but it sounds like you still have to be careful.

Slow Code wrote:
"That`s what happens when you lower standards,----."

Technological progress eliminates the need for operator expertise and close equipment supervision.

A First Class Licensed Radiotelephone Operator is no longer justified or needed to constantly supervise a type-accepted broadcast transamitter designed to only operate when it is operating within the rules (no challenge with modern technology). A less technically adept person can tell if operation is normal.

Amateur operation is different. Equipment need not be type-accepted, but it must adhere to the rules just the same. An amateur operator is licensed as such and that defines the "amateur radio operator". The "ham" may or may not be interested in experimentation. The only requirement is that he not violate the rules.

Difference between amateur and CB radio is CB can be used in business. Amateur radio cannot.

CW radiotelegraphy was obsolete when radiotelephony appeared. This is similar to obsolescence of the horse when the motor vehicle appeared. Communications and transportation have moved on but Morse and horse fanatics linger.

Amateur radio appliance operators are fine so long as the rules are enforced. We should seek them and welcome them to the hobby.

Best regards, Richard Harrison, KB5WZI

==========
The results of such experiments would probably generate far less interest than BLE's original work and would not be of great use. But somebody might possibly create a reputation out of it.

To repeat BLE's experiments at HF, and to be of use, would require measurements to be made over a wide range of frequencies, over various lengths of radials, over various numbers of radials, over a range of soil resistivities and over a range of soil permittivities.

Complexity and cost would be enormous. Financial returns would be relatively small. Who would invest in such a project? How many people wishing to erect a 28 MHz vertical over a set of radials need more knowledge than what already exists. Even CB-ers could do it!

It would be far more economic, with a guessed understanding of how radials work, to write and dedicate a computer program to do the job. With a little more tidying-up, program Radial_3 would do. And it's FREE to USA citizens. No licence required! ;o)

Reg.

------------ REPLY SEPARATOR ------------

If you go to the Icom website, they acknowledge the problem and have a
serial number posted, after which the problem is fixed. That serial
number happened a long time ago, so recent production should be ok.

Just verify the serial number.

Bill, W6WRT

Nope. It's "Amateur Radio Operator", not "Amateur Radio Constructor".

I'll ask again: What does construction skill have to do with operator
skill?

Be sure that the Gutters are not grounded. If you have Aluminum Siding, the
gutters maybe attached to the siding. A quick check with an ohmmeter should
verify that.
Other wise the gutters make a great antenna.

A friend of mine locally here tried one. In contest operations it made far too much phase noise over a fairly wide chunk of band, making it a bad actor when other contest stations are operating within a mile or so.

He replaced it with a 756Pro and, having used that radio, I would have to say it is probably the 2nd best receiver I've ever had my hands on in more than 40 years of commercial and amateur radio operation (the winner being a $20k Hagenuk).

Tell that to anyone that uses Aurora! What is
that intenmittant buzz on my radio?? Why can't I
figure out where this interference is comming
from? Can I get my power company to eliminate
it? And, by the very nature of it, digital
wont decode it (too much distortion).
Oh, well! And, BTW,1) The First Class Phone
is no longer issued (only General), and 2),
the ONLY people NEEDING one is for Marine , and
for Airlines! These havent been required for
two way, nor broadcast services for years, now!
The only reason for the requirement for those
two services, are because of International Treaty!

1305. High voltage switch/relays for antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-27 01:31:53 UTC
From: TF3KX <tf3kx@simnet.is>
Message-ID: <1153963913.849931.144990@i42g2000cwa.googlegroups.com>
Source record: 55542

Hello:

I am contemplating constructing an antenna where a center-fed HALF WAVE will be bent in a loop, only to be isolated at the almost-touching ends by a relay or some other means of a remotely controlled switch. When the relay contacts are open I will have very high RF voltages between the contacts, probably "a few KV" or even more. Are there any suggestions on where I could find a relay, if any, for this? Or any other means for doing this? An additional constraint is that the switching device needs to be light and small (say, 1-2 oz or 20-50 grams). Some ideas I have come up with are:

- A small vacuum relay (supplier, type?).
- A home-made relay, providing more contact spacing than usually available.
- A DC-motor (toy-type) driven mechanism to open and close contacts.
- A mercury switch that could be tilted to make or break the contacts.
- A string-operated switch to open and close the contacts (would run up the antenna mast).

Any comments or suggestions?

73 - Kristinn, TF3KX

TF3KX wrote:

> Any comments or suggestions?

I assume you are going to switch the loop for lowest band into a bent dipole, and close the relay on higher bands.

You might consider a trap, because a relay would have to be very special at any power level. You are deealing with much more than twice the voltage at the ends of a normal dipole from contact to contact.

I think your only hope for a relay is a high voltage vacuum relay with wide terminal spacing and good coil insulation. One of the large high voltage glass vacuum relays would be best.

It might be possible to build a trap and adjust antenna length so it would work, but the trap would have to be very special in construction. It may not be practical.

The first BCB shortwave radio station I remember hearing was also
HCJB. Grandmother listened to it and netherlands antilles every day.
She bought the radio when I was about 7 or so and I helped her unpack
it. She showed me about where to find the station. I tuned it until
I hear "To God Be The Glory, Great Things He Has Done" tune and it
constantly repeat. She was awful proud of me. I listened to it for
years. I haven't listened to sw bc much in quite a while. My 706
MKII should do well, but for some reason, I guess I just don't.

Siding works too. :) depending on if it's grounded or not.

I think my strangest antenna was when I connected wires from my tuner
to each of the two window screens in the corner room. I worked
california from Georgia on 10 meters. :)

1310. batter question

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-27 02:38:49 UTC
From: ml <m@di.net>
Message-ID: <m-8C7C2A.22384526072006@news.verizon.net>
Source record: 55547

ok this isn't exactly a antenna question but hope it's ok

I have a super powergate ... and a 8g27 gel battery

i got a battery from a friend a smaller 25am battery , cant figure out the chemestry but seems like agm

so the battery is smaller sized, and perhaps/probably different type(not gel)

i therefore presumed i couldn't parrallel them as they would get different charge rates and poof

but someone said that it's ok and each battery will just draw what it needs as it's resistance changes (presuming that both batteries were at equal Volts when i hook them up initially to avoid bat a charging bat b

but unsure and feel i should double check a 8g27 blowing up in the house wouldn't be fun

thanks

Reg, with the antenna we have established as our test model:
All wires #14, monopole 9 m, 36 X 10m radials 25 mm below
ground. Ground parameters Er = 16, resistivity 150 ohm-m.
I have calculated the radiation efficiency including the surface
wave. What is interesting is that the surface wave contributes
very little at elevation angles over 10 degrees.

For 100 W input the total radiated power, not considering
the surface wave, is 31 W. When the surface wave is
included the total radiated power is 36 W.

If you are unsure then fit a diode on the + terminal of each battery (one that can handle the current you are going to draw) with the cathode away from the battery and connect the cathode ends of the diodes together, take your power from this point.

Hey presto the batteries will 'ignore' each other.

If you are going to charge them together you can do the same on the + lead of the charger, this time the cathode goes to the battery and the anode goes to the charger.

I used to parallel NiCads like this before hi capacity NiMhs came on the market. (NiCad batteries do NOT like to be parallel connected at all!)

Hope this helps

Brian

==========
Frank,

So the missing 64 watts, if not dissipated in the radials must be dissipated in the soil under the antenna.

To prove something, what is the efficiency when the ground is sea water. Resistivity = 0.22 ohm-metres and permittivity = 80.

PLEASE CONFIRM THE NUMBER OF RADIALS.

I thought you were unable to model 36 radials. Were you using only 1 radial? With only 1 radial my program makes efficiency = 28 percent. Which would be satisfactory agreement with your 36 %)

Or did you substitute the radial system with a lumped resistance of 5 ohms which I suggested could be used when estimating efficiency?

Reg.

My strangest was a six meter dipole buried about a foot underground. I
worked one station about ten miles away.

About a week later I received my WAE award. (Worked All Earthworms).

IMHO two high power relays would be an option, about 10 inches seperated
from each other.

For example Titanex (www.titanex.de) sells good High Power Ceramics
Relais for this purpose:
http://www.titanex.de/frames/acc.html#UB6-9 (HPRL) with power handling
of 5 kW each.

Palstar in the US use high power relais in some of theire antenna
tuners, but those relays are not ceramic.

Good luck!

I have a discone antenna on my roof and the mast is grounded to the earth with #8 solid wire with a ground rod.
I want to use lmr-400 wire for app 50 ft to the scanner. Is it necessary to install the cable with an in-line arrestor ? I hate to have to add more connectors if it isnt necessary...I always unplug the scanner from my cable, rg-58, when Im not using it.....Any thoughts.....Thanks Mike

Well, it's up to you. An arrester is going to be safer than
no arrester, but if you are unplugging, maybe you don't need
it . But even then, that depends if you actually throw the coax
outside when not in use. If you do, maybe you can get by,
assuming you never forget to unplug. But if you are just unplugging
and leaving it in the room, I'd for sure have an arrester.
You do not want an unprotected direct path to the house interior..
No bueno! I don't use arresters, but I'm cheap, and I always
ground the unused coax's *outside* to a strip of grounded SO-239's.
My mast is grounded well also. I've taken two direct strikes that
I'm aware of, and have had no damage at all to anything. Most goes
to ground at the mast, and whatever is left on the feedlines goes to
ground at the window ground. Both grounds are tied together and are
the same appx potential. Some energy does go to ground at the window.
I can hear it arc on mast strikes, or sometimes even close indirect
strikes.
You wouldn't really want that in the house with you unprotected.

How did you wind up with a dipole buried underground? Were you trying
to make a resonant dummy load?

Dunno.. I used to use 24 volt relays that normally are used for
fan motors, etc, but I never fed at a high voltage point. I did run
a lot of power though. They always worked fine, but who knows
with a real high potential.. Might arc over.. I've heard tell of one
kinda weird method that supposably will work. I've never tried it
though. You run a line of coax from that open point on the antenna,
to the shack, and use a switch on the end of the coax to open
and close. Like I say, I've never tried it myself, so it' may or
may not work...

About three years ago I disconnected my dipole antenna from my IC-706
and tossed the pl-259 connector into my plastic trash can. A little
later the power went out and I heard a sizzle. The white trash can
was glowing from the arcs going across the connector. It wasn't
bright, but in the dark it was noticeable. There wasn't any lightning
or thunder at that time. It really got me to thinking about what the
radio would be like if i had left it plugged in. I unplug my rigs
much more often now.

See ARRL Antenna Compendium Vol 5

W7JGM, tells of his experiences using a buried long wire antenna. He compared it to high inverted V and he reported that most of the time the signal strength was close to the same. He did report that when the ground got wet his signal dropped.

Regardless

After reading KM5KG's web page describing buried dipole dummy loads, i will keep my coax and copper in the air! But hey Diamond and Comet sell vertical antennas with resistors in them and users report good results. Performance is indeed in the mind of the user.

This is not quite accurate. If he signed a contract, i.e. agreed to a set of CC&Rs in a private subdivision at the time of purchase, he is obliged to honor the contract. Contract law in private, not public, domain trumps PRB-1.

>
> Good luck!

I would say good luck also if I assumed a relay could actually be rated for a certain number of "kW".

A relay that easily takes 50kW in a 50 ohm system could fail at 100 watts in an application like this, so it is foolish to even look at power ratings in other applications.

In this case when the relay is open he will have very high voltages across the contacts even with very modest power. When the relay is closed he will have a few amps of current at low power up to 5 or 10 amps at kilowatt levels.

Not only will he have high voltage between contacts, he will have high voltages from the contact to ground.

That virtually excludes conventional relays, and it even excludes many types of vacuum relays. The popular ceramic vacuum relays normally have too low of coil to contact breakdown plus the terninal spacing is much less than 1/2 inch.

He probably can get by with a conventional ceramic vacuum relay like an RJ1A (about $50 US surplus) at low power levels (normally considered a "5kW relay, whatever that means) , but if he runs more than a few hundred watts and especially if there is moisture in the air he will need a HV glass vacuum with opposing terminals for contacts and a long insulation bar on the transfer solenoid bar.

Power levels depend on the application, and he has picked about the toughest application I can think of.

I have some aluminum 50 ohm Heliax I need connectors for, but the part number is worn off the cable.

It is 7/8th inch. It is copper clad aluminum solid center conductor. The shield is a lightly heliax ribbed aluminum shield. It's a quality cable so I hate to toss it, and no...even though I have a lathe I don't want to make conectors. It is going on a big tower and I can't risk having connectors fail, so I need the proper connectors.

Does this cable sound like anything anyone knows about?

Thanks, Tom

There was an article in QST about underground antennas. It might have
been an April fool's article but it was so long ago I don't remember
for sure. I was 14 or 15 and anything seemed possible. :-)

Years later I came to the conclusion that I worked the other guy with
incidental radiation from the rig itself and/or the coax feedline, not
the antenna itself.

I performed this same function in Arizona with a $5 relay.
There is a surplus store beside the freeway in South Phoenix.
They carry surplus relays from the local power company. Some
of those relays are high voltage rated. I choose a SPST relay
that had four contacts. Two contacts were about an inch apart
and, when energized, were shorted by an insulated shorting bar.
When not energized, there was a total of at least one inch of
air gap in the contact path, maybe more. The contacts were
about 1/4" in diameter.

I was running 100 watts. I borrowed a differential high voltage
scope and measured the peak to peak voltage between the ends of
my loop to be somewhat less than ~2500 volts. This was a full
wave 40m loop broken in the middle and tuned to resonance on 80m.
I tested it in increasing increments of 10 watts all the way to
100 watts with no problem. It was before the monsoon season so
the humidity was low. A couple of months later, a severe
thunderstorm broke my upper 2x2 support and brought the whole
thing tumbling down.

Reg,

The antenna has thirty-six 10 m radials, 25 mm below ground. The input impedance at 8.07 MHz is 36.3 - j 2.0. I used 0.2 ohm-m for sea water resistivity as it seems to the accepted standard. The radiation efficiency, not including the surface wave, is 93.6 %. I can add the surface wave if you are interested, but it is a little tedious to convert the far field surface wave, in cylindrical coordinates, to normalized spherical coordinates; which is the form NEC produces for the sky-wave components.

Back in the '50's, Larsen E. Rapp got me with one of those
articles. He said we could create an "amplitude discriminator"
with "back to back limiters". That way, we could simply
discriminate by tuning out the strong signal and tuning
in the weak signal. I asked W5OLV how to build back to
back limiters. He couldn't stop laughing.

Too many types to tell from what you have said. Is it jacketed or is
the outer "ribbed" shield bare? Are you sure you can't find ANY numbers
or lettering at all on it that might help? Short of cutting off a foot
and running it around to various Radio maintenance shops and Cable TV
providers, I dont know how to ID unlabeled material.

I still like to think about an article in "Popular Electronics" back in the late 50's or early 60's about "CONTRA POLAR ENERGY". This principal worked in the exact opposite manner to regular energy: electric lamps absorbed light, heaters froze etc. It got me for many years until someone queried PE about it years later. The cat was let out out the bag. To bad it was an interesting concept.

Frank, the reason I asked what the efficiency is when using sea water was to prove your own efficiency calculations.

With sea water the efficiency should be very near to 100 percent. You get 93% WITHOUT taking the surface wave into account. To make youself happy you could include the surface wave.

Program Radial_3, with sea water, makes efficiency 98 percent which I'm confident is near enough correct. Most of the loss is in the HF resistance of the 14-gauge antenna wire.

==========

It's beginning to look as though the oft-quoted formula -

Efficiency = Rrad / (Rrad + Rloss)

is very much in error. This formula is quoted in all the ARRL books and other learned magazines. I will correct my program to agree better with NEC4 even though the absolute value of efficiency is not important and is used only as an indication to maximise effectiveness of the radial system.

I await your experiments to determine the impedance Zo of ONE radial wire and the approximate distance at which it occurs.

You can do N = 36 radials at a later date.
Thank you very much.

Reg.

You can purchase the course book for around $40.00 USD from the ARRL.
Doing that you'll have a good reference book for future use at hand. The
book is the complete course word for word and very well written. Plus the
money you'll save will pay for EZNEC with a little pocket change left over.

H. R. 42

One Hundred Ninth Congress
of the
United States of America
AT THE SECOND SESSION

Begun and held at the City of Washington on Tuesday, the third day of
January, two thousand and six

An Act
To ensure that the right of an individual to display the flag of the
United States on residential property not be abridged.

Be it enacted by the Senate and House of Representatives of the United
States of America in Congress assembled,

SECTION 1. SHORT TITLE.
This Act may be cited as the ``Freedom to Display the American Flag
Act of 2005''.

SEC. 2. DEFINITIONS.
For purposes of this Act--
(1) the term ``flag of the United States'' has the meaning given the
term ``flag, standard, colors, or ensign'' under section 3 of title 4,
United States Code;
(2) the terms ``condominium association'' and ``cooperative
association'' have the meanings given such terms under section 604 of
Public Law 96399 (15 U.S.C. 3603);
(3) the term ``residential real estate management association'' has
the meaning given such term under section 528 of the Internal Revenue
Code of 1986 (26 U.S.C. 528); and
(4) the term ``member''--
(A) as used with respect to a condominium association, means an
owner of a condominium unit (as defined under section 604 of Public
Law 96399 (15 U.S.C. 3603)) within such association;
(B) as used with respect to a cooperative association, means a
cooperative unit owner (as defined under section 604 of Public Law
96399 (15 U.S.C. 3603)) within such association; and
(C) as used with respect to a residential real estate management

association, means an owner of a residential property within a subdivision, development, or similar area subject to any policy or restriction adopted by such associa tion.

SEC. 3. RIGHT TO DISPLAY THE FLAG OF THE UNITED STATES.
A condominium association, cooperative association, or residential real estate management association may not adopt or enforce any policy, or enter into any agreement, that would restrict or prevent a member of the association from displaying the flag of the United States on residential property within the association with respect to which such member has a separate ownership interest or a right to exclusive possession or use.

SEC. 4. LIMITATIONS. H. R. 42--2
Nothing in this Act shall be considered to permit any display or use that is inconsistent with--
(1) any provision of chapter 1 of title 4, United States Code, or any rule or custom pertaining to the proper display or use of the flag of the United States (as established pursuant to such chapter or any otherwise applicable provision of law);
or
(2) any reasonable restriction pertaining to the time, place, or manner of displaying the flag of the United States necessary to protect a substantial interest of the condominium association, cooperative association, or residential real estate management association.

Reg,

The efficiency, including the surface wave, is 96%. There is also
a 2% copper loss. With perfect conductors the efficiency
would then be 98%. All figures from 100 W input.

I have not forgotten the single radial computation.

Frank

Source record: 55488

At my summer QTH I mounted a simple wire delta loop, that I feed with a standard 300-home TV ribbon (I prefer symmetrical antennas, as having a good ground is not always that simple).

In the station I have an asymmetrical tuner, so, not to get RF on my radio, I must use a balun in between the tuner and the 300-ohm ribbon coming from the antenna.

I am not so enthusiast about using a common 1:1 or 4:1 toroidal transformer, as I am not sure on how those transformers behave across the very wide impedance range that they see at the ribbon end when operating 7 through 28 MHz.

So, I decided to instead use an RF choke that quenches the common mode RF. I firstly built a thick ferrite core by taping together five 3/8"OD ferrite rods, 6-inch long. I then made 10 turns of a very thick insulated red-black twin lead on it. The turns are widely spaced, so as to have low capacitance between adjacent turns.

The system works fine and gives me no problems, but I would like to hear some opinions on that approach, as I do not often see it proposed as a solution for feeding balanced lines.

Should I instead wish to try a common toroidal transformer, would you better use the 1:1 or the 4:1 version? My reasoning is as follows: unless my delta loop resonates on one of the ham bands, its impedance will generally be rather high. So, using a 4:1 balun would facilitate the tuner task. Any comment on that too?

Thanks and 73

Hi Tony,

Sounds good. The only unknown is the ferrite properties for the range
of RF.
>

You can also try putting a 1:1 current BalUn (or choke) on the coax
going from your rig to the tuner.

However, you do not say you had any problems to begin with. If you
are trying to achieve symmetry, you need to be able to measure how
close, or how far away you are. If you cannot do this, then you don't
know how much improvement you are making.

Frank,

The efficiency formula is incomplete rather than being in error.

In the case of radial systems it could be something like -

Efficiency = Rr / (Rr + Rradials + Rsoilsurface) .

When soil resistivity becomes very small, efficiency approaches 100 percent and the error when compared with NEC4 reduces to zero. The error is therefore a function of soil resistivity.

Congratulations. You have just re-invented the choke balun. It's what many people use. It is the best choice. Very often it is wound on a ferrite ring. It has no impedance or turns ratio.

Or it may consist of a number of ferrite sleeves which slide over the transmission line.

It is a mistake to use a balun between tuner and transmission line which has a definite impedance or turns ratio.

Reg.

Can't find any readable numbers.

It is probably older cable, but it is in good shape and hate to toss
it.

It is 50 ohm. 7/8 inch. Tough thin black jacket, bare aluminum with
much smaller ribs than normal Andrews heliax, closed cell foam
insulation, copper clad solid core aluminum center conductor.

Just thought someone might know. Can't find anything anywhere myself,
so I might have to just toss it out.

So, Rloss = Rradials + Rsoilsurface.

The components of Rloss change depending on the antenna being studied.

But, Efficiency is still % = (Rr/(Rr + Rloss))*100

I'm not familiar with any 50 ohm heliax with non-copper sheild. I am posting your query on another list. We'll see if there are any responses.

BTW, how do you know its 50 ohm? Every aluminum jacketed heliax I've
come across has been 70 ohm, used in the video industry.

<<<<>>< thanks very much for the help i sorta thought about diodes but figured hen say both bateries are charged or even 1 how would my charger be able to 'sence' this from the batery? and how would it say stop charging bat a but still flow V to the 2nd batt? "if they are parrrallel"
so my fear is in charging mode 1 batt might get way overcharged ????

I dont see the word flagpole anywhere in this legislation...just
flag....HOA's can make a law that flags will be on a 4 foot rod if they
want....and can even tell you what SIZE flag your allowed!

But yea ...you can fly Old Glory!

This law really dont help that much.

That was my think, too. I've worked with both the 1/2 inch and the 3/4
inch cable TV hardline before. <http://jonz.net/W3DHJ/catvhardline.html>

But, then, I never worked with the 7/8 inch stuff and I've never seen
any cable TV hardline that was "ribbed".

If the delta loop's impedance is rather high and the
feedline is an odd multiple of 1/4 wavelengths, what
impedance will the balun see?

2 + 3 + 1 doesn't ever equal 6 inches. 2 inches + 3 inches + 1 inch
does, however, and if you build something that is
2 inches + 3 inches + 1 inch, you'll most likely verify it with
a ruler just to see how close you got.

Where did you measure the 7/8 ? Only 50 Ohm Heliax I have used was 1/2, but
that measures about 5/8 OD. BTW, other than Andrew, Times Microwave also
makes cable like that. Can't recall what they call it.

I am trying to understand forward and reflection power
throught practical circuits , instead of going through books.

I found forward/reverse power meters measure reverse
power by measuring the phase difference between current
and voltage at load terminals. If current and voltage
are in phase, there is no reflection . am i correct ?

if it is correct ,
if transmitter has 50+j0 ohm output impedance , and if i connect
antenna tuned to 100+j0 ohm. (assume no long cable is used ,
directly connected) , reverse power is zero ?

regards,
palani

1379. Capacitive Hat

Newsgroup: rec.radio.amateur.antenna

I know a capacitive hat (or capacitance hat) lowers the resonant frequency of a whip by electrically lengthening it, but by how much? When I was in the service, one of our techs loaded an AFRTS BCB transmitter (1520 kHz, I think) into a 35-foot whip that had a capacitive hat. The hat was a five foot diameter ring of #10 wire with four spokes off the top of the whip. I don't recall (or never knew) what other matching he did. 50 watts went about ten miles, so it worked OK, not great.

The ARRL antenna book makes it look like the physical length is about 2/3 of the electrical length (60 degrees physical length plus 30 degrees from the hat).

Hi OM,

The hat replaces roughly double its length in height - or so goes one
proportions of one magic formula. So, for your example of:
>a 35-foot whip that had a capacitive hat. The hat was a five
>foot diameter ring of #10 wire with four spokes off the top of the whip.
hat would say it is equivalent to a 40 foot radiator (35 + 2 ï¿½ 2.5).
I've often wondered why anyone would go to the trouble to wrestle with
the mechanical details of keeping a top hat aloft, when they couldn't
manage what would be 5 additional feet of whip in this case. Top hats
built out of guys is another story, but free-standing hats seems more
like adornment than being necessity driven.

You may note this doesn't come even remotely close to resonant for
1520 KHz - if that was the implication in your posting. Further, it
would be an amazing top hat that could for a 35 foot whip.

Hi Palani,

The remainder of your post suggests you should go through the books.
>
>I found forward/reverse power meters measure reverse
>power by measuring the phase difference between current
>and voltage at load terminals.

WRONG. However, what you say is right by parts. They measure
voltage, they measure current, and they measure differences, but not
in the simple manner you describe. The sum of the parts does not
equal the total of the statement.

>If current and voltage
>are in phase, there is no reflection . am i correct ?

WRONG. See following:
>
>if it is correct ,
>if transmitter has 50+j0 ohm output impedance , and if i connect
>antenna tuned to 100+j0 ohm. (assume no long cable is used ,
>directly connected) , reverse power is zero ?

12% of the power is reflected with a 2:1 (100:50) mismatch, not zero.
Current and voltage are in phase (resistive load by your definition of
100+j0 ohm).

There is a 'grasswire' antenna. It is basically a wire run on the
ground. Not great but does claim to have low angle radiation.

No. Assuming Z0 is purely resistive, here's what it
takes to make your statement true:

If current and voltage are in phase *at every point*
up and down a transmission line, there is no reflection.

Just to be sure we have cause and effect straight, the
statement should probably be:

Assuming the presence of a signal, if there are no
reflections on a purely resistive Z0 transmission line,
the current and voltage will be in phase at every point
on the transmission line.

I took the course and purchased the EZNEC + v4.0.

For me it was the right way to go. Having the pressure and
responsibility of completing the course kept me on topic in a timely
fashion. I continue to use the reference material and the program.

The EZNEC program allows you to compare a lot of different conditions
without expending unnecessary resources.

Sal,

A capacitance hat allows you to drive your car into the garage without
breaking off a whip of 15 feet equivalent height.

A capacitance hat loads a short vertical without suffering the loss in
a loading coil.

To calculate capacitance of a hat, above an antenna of given height,
with N spokes of given length, surrounded by a halo, plus resonant
frequency, download program TOPHAT from website below.

The program also calculates L and C values of the tuner. The whole
job can be done in a couple of minutes.

Message-ID: <1154100643.691199.3530@b28g2000cwb.googlegroups.com>
Source record: 55432

Hello, I have a vertical antenna that is tuned via taps on a coil at the base. As I was moving the tap the other day I had the idea...why not replace the tapped coil with a roller inductor? This would certainly make tuning easier and as long as the roller is protected from the elements should work as good as a fixed coil. Is there any reason why this wouldnt' work? Has anybody else modified or built an antenna using such a system? (For the record, the antenna is a Hy-Gain AV18VS. I used to use it only on the low bands and as such rarely had to move the tap, but now that I have an amp and this is the only antenna I have that can handle power, I've been using it more often and on more bands).

> I await your experiments to determine the impedance Zo of ONE radial
> wire and the approximate distance at which it occurs.
>
> You can do N = 36 radials at a later date.
> Thank you very much.

Reg, I started to do an analysis of a single radial monopole.
Beginning with a 1 meter length radial I compared the results
with "radial_3". There is such a huge discrepancy between
the programs I wondered if I had made an error someplace.

Just to confirm the antenna dimensions: 9 m monopole,
with a 1 m radial, 25 mm below ground. All wires # 14 AWG,
and the test frequency 8.07 MHz. Ground Er = 16,
resistivity 150 ohm-meters.

"radial_3":
Antenna input Z = 34.21 - j 26.2, and;
radial input Z = 82.7 - j 62.3.

"NEC 4.1":
antenna input Z = 137.8 - j 81.8, and;
radial input Z = 101.4 - j 79.1.

Interesting to note that the input impedance determined
by radial_3 is very close to an ideal monopole above
a perfectly conducting ground.

Source record: 55434

Sirs:

I am a programmer and electrician, but not a radio person! I am sending an experimental balloon to over 100,000 ft. I have purchased two 900MHz RF Aerocomm ConnexLink Radios. The radios have a power of 1000 m.a., which states it will transmit and receive up to 20 miles line of sight. I do realize that this is probably under ideal circumstances and will not likely be the case when I actually deploy. I would be interested in purchasing some antennas which would somehow increase the range. What sort of characteristics make up a good antenna for what I want to do? It is possible that someone could find me one that would work with my project? Also, anything you might contribute concerning radio transmission would be very much appreciated.
Money is no object for this experiment, so any ideas you have are very much welcome.

Thanks,
Brett

Frank, I am not interested is what happens at very short lengths or
what Radial_3 makes of it.

To determine Zo, start around 10 metres.

If very little happens to input impedance between 10 and and 15 metres
then you already have Zo = Zin = Ro + jXo.

Neither am I interested in efficiency or antenna input impedance..
The problem of Efficiency has already been sorted out.

All I wish to know is Zin = Zo of a single radial, at various lengths
greater than about 10 metres, of diameter = 1.64mm, depth = 25mm,
ground resistivity = 150 ohm-metres, permittivity = 16, at a frequency
of about 8.07 MHz.

That is the input impedance of one radial when the attenuation is
about 20dB or greater.

To summarise, I wish to know Zo = Ro + jXo for one radial.

Reg.

Hi Brett .

Is it possible that your radio power level is 1,000 m.w. rather than 1000
m.a.?

I think this 'antenna' problem can be easily/inexpensively solved. if the
location of the balloon is known.

Jerry

Reg, this whole thread started because bizarre things happen with
Radial_3 with short radials.

You can go ahead and put a caveat in it if you like, but it's wrong at
short lengths and that fact needs to be made clear to users of the
program, before they install a radial system of 120 2m radials on 80m
and find that it's a terrible ground system.

The question that I want answered is how to optimize my radial system,
and I think at this point, I shall be consulting a document entitled
"Maximum Gain Radial Ground Systems for Vertical Antennas" by K3LC.

Anyone have other suggestions for sources of material for optimum
radial selection given a certain length of wire?

73,
Dan

Reg, the radial impedance rapidly converges to 101.6 + j 21.1.

10 m -- radial Z = 102 + j 20.99
12 m -- radial Z = 101.3 + j 21.1
14 m -- radial Z = 101.65 + j 21.32
16 m -- radial Z = 101.7 + j 21.1
18 m -- radial Z = 101.615 + j 21.1
20 m -- radial Z = 101.61 + j 21.11

Just about any antenna will work . I would look into a 1/4 wave antenna mounted upside down so it is pointed down for the balloon. I hope you ment 1,000 mw, or one watt of power for the transmitter. I have heard the hams in the space shuttle and space station with a 5/8 wavelength on my car. They only run a few watts and are over 100 miles up. Also talked with an airplane at 40,000 feet that was over 150 miles away. I was using a 10 watt radio and a small beam. He was using a handy talkey with maybe 5 watts inside the plane. Unless you are under a bunch of trees , there is not much beter conditions than to be line of sight. While it will probably be too small to see without a telescope, as long as the balloon is in sight almost anything will work.

1413. Re: adaptive beamforming

Source record: 55450

well, 'adaptive beamforming' is two words...

'beamforming' means forming a directional 'beam' using an antenna. be it a simple parasitic array like yagi's or a complex array of driven elements like a flat panel radar. most often when you talk about beamforming it is more like the radar arrays or other large array that combines signals from many small antennas to form a very directional beam.

'adaptive' means forming the beam in a way that makes it work better in the environment, or adapt to it's surroundings. this is often used to form beams to maximize a received signal while notching out interference. so you use an algorithm to measure s/n ratio or some other parameter and adjust power and phasing of the individual elements to get the best signal you can. its harder to adapt a transmitting antenna since you need some kind of feedback from the far end to let you know if the beam is getting better or worse as you adjust it.

Yes it has been done but not without its problems. Stopping the coil in
the right place, roller contact with the coil... can all be a problem.
I had good luck using a tapped coil and using relays to switch the taps
much as is done with an auto tuner. Some radios would allow the coil(s)
to be switched automatically with the help of a little extra equipment.
Just using manual control is not too bad. I think I saw a circuit to be
used with ICOM radio that controls relays by utilizing a DC voltage
that changes with band selection/frequecy. This was fed to a group of
comparator circiuts that drove the relays. I know of at least one
person who has tried this and it proved to be a good route for
lightning to get in his radio so my preference is the manual switch
controling relays. I dont know how this would work with your radio. The
only one I am familar with using this arrangemet was a 30+ ft whip
using a big flat metal roof as a couterpoise.

So that would have its pattern null pointed down at the earth?

Not to imply that the balloon would necessarily be directly above the
observer(s), but if and when it was at the zenith, it would be
relatively hard to hear.

The OP hasn't told us the elevation angles of the locations of the
balloon in flight, how fast it is likely to spin, data rate or
equivalent (eg is this intended to send images back?), etc... they are
all relevant to commenting on suitability of the 1000mA??? radio, and
the type of antennas for the balloon and ground station(s).

Owen

For an amateur balloon project, see

I did mean to comment on the temperature spec for the radio. The
temperature in the troposhere can be as low at -50 to -75 deg C, will
the radio get cold enough in transit to fail (eg battery failure,
condensation etc).

At an altitude of 100,000 feet 1000 mw [1 watt] should reach to the radio horizon of about 300 miles assuming a good receiver on the far end of the range.

A vertically polarized 1/2 wavelength antenna should work fine. At least it would be my starting point. Second option would be an inverted [upside down] 1/4 wavelength ground plane. Either antenna is not expensive.

What information is to be transmitted? If you are looking for moderate speed telemetry then a path loss versus error rate study needs to be done. If data is being transmitted a gain antenna may be required at the receiver. Gain antennas are not expensive and the antenna needs to be pointed at and follow the balloon's flight path.

>
==========================================
Frank,

Excellent results! The radial has already converged on Zo = 102 + j21
at a distance of 10 metres. Just where Radial_3 predicts it should.

The magnitude of Zo is within 20 percent of NEC4 and the impedance
angle is in the right ball-park with the correct sign.

Now work downwards from 10 metres, to about 7.5 metres, the 3/4-wave
resonant point, to find the point where Zin has truly diverged from
Zo. You will have to work in gradually smaller increments.

Could you go down to the 1/2-wave resonant point at about 4 metres?

You will now be able to see what I'm heading for.

By the way, how much hard labour is all this causing you? Don't try
to tell me what you are actually doing because I havn't the foggiest
idea.
----
Reg,

A high gain rubber ducky is an oxymoron.

Dave,

Thanks for responding.

Given the need for "stealth" antennas, Is there /are there design(s)
that create small footprint antennas that function as larger traditional
ones?

Can a longwire be divided into small segments that are independently
controlled such that the sum of the parts behave differently than the
whole?...and can this effect be altered via software?

Has anyone been working on this approach?

John

I have the chance to buy a RF-2601 new in its boxes. Can anyone advise me if an RF-2601 and its control unit are a stand alone installation? The data sheet advises it is designed to operate with Harris transmitter. Do they come with an instruction manual? Is further info available? Do you need to pressurise with nitrogen to achieve full specs of 1KW average power?

1425. Re: Radiating Efficiency

Newsgroup: rec.radio.amateur.antenna

From: Roy Lewallen <w7el@eznec.com>
Message-ID: <12clp9b5e3ual1c@corp.supernews.com>
Source record: 55462

I've explained this to Reg many times before, but somehow it doesn't seem to sink in. Here's the explanation again.

Reg Edwards wrote:
> "Frank's" wrote
>>>> W7EL tells us that EZNEC doesn't display the surface
>>>> wave which obviously contains power. Would that affect
>>>> the efficiency using the integration technique?
> ====================================
>
> The surface or ground wave is the most important fraction of total
> radiated power.

It's important only to AM broadcasters and others communicating at low frequencies, and to HF operators interested in working distances of only a few miles. At HF, it decays to a negligibly low value within a few miles, and so is no importance at all beyond that distance.

> The correct radiation pattern of a vertical antenna
> shows maximum radiation along the ground. Angle of maximum radiation =
> 0 degrees.

Let's consider that for a moment. The surface wave decays rapidly. So the "correct" radiation pattern as described by Reg changes dramatically with distance. At HF, the pattern at one mile will be strikingly different from the pattern at 20 miles; the first will be maximum at zero elevation angle, the latter won't. So if you want this kind of "correct" pattern, you'll have to specify the distance from the antenna. Once you're a few miles away, at HF, the pattern becomes constant with distance, because the surface wave has decayed to essentially zero. Then you have the pattern which is useful in determining communication beyond a few miles. (This is the pattern reported by EZNEC and NEC as the "far field" pattern.) Reg's "correct" pattern isn't useful for anything but short distance communication, and isn't valid except at the distance specified.

> When deducing efficiency, to omit power radiated along the ground from
> the hemispherical integration will result in serious error.

Well, it kind of depends what you lump in with losses when calculating efficiency. The classical formula for antenna efficiency, Rrad/(Rrad + Rloss), generally applies only to the antenna itself and near field losses such as ground system losses. So power in the surface wave is considered to be "radiation", and if you want to calculate this efficiency by dividing the power in the radiated field by the power from the sources, you would have to include the surface wave in the

calculation. However, for people communicating more than a few miles, the surface wave power, which is dissipated in the ground within a few miles of the antenna, is just as lost as power dissipated in the wires or the ground system. So if you consider "radiated power" to be power radiated beyond a few miles and "loss" to be the rest, then you can lump the surface wave power into the "loss" portion. If you do that, the efficiency is correctly reported by EZNEC or NEC's average gain function.

> (Efficiency by NEC4) / (Efficiency by formula) = 0.38

I won't comment on that because I haven't a clue where it came from.

> I can imagine other losses in addition to loss in the radials but to
> have the other losses several times greater is a bit much. Where are
> these large losses? Are they in the soil surface - the only other
> candidate?

The surface wave power is indeed dissipated in the soil within a few miles of the antenna.

http://www.valcom.ca/Guelph/products/highfreq/as3772b-u_photo.html This is
built for navy shipboard use so it may be "scary expensive." These are
virtually indestructible. You have to hit one with a crane boom to break
it. It is exactly what you described in your last paragraph. This size
whip covers 2 - 30 MHz with a tuner.

The Navy has used many 35-foot whips over the years. There were
five-section versions, but any you found now would probably be too corroded
to be of use.

Cool - you can cut the rods in half and transport them... since you have four rods, you'll end up with eight equal lengths once cut, of four feet long. There are, however some cons here (I'll get to that). Depending on your local geology and soil content, I would advise checking the conductivity of the soil in the summer, during a dry spell. Depending on the arrangement of the rods, it might also be a good idea to consider a "halo" type ground instead of maybe just sticking them in the ground and then connecting them in parallel - but I'm not sure what your plans are exactly. There are also chemicals which you can use to dope the soil you plan on inserting the rods into... usually an inexpensive ion-rich salt solution, although with such implementation, close attention usually needs to be paid to oxidation / corrosion within the first few years. If water is no object, put in a "soaker system." You can even do this "off the (water) grid" by using a cistern or large water collection reservoir.

Overall, I'd say your best bet would be to leave those suckers as long as possible and save yourself the time and headache. Since lightning tends to follow paths of least resistance, avoid sharp turns in your grounding strap or wire - additionally, short rods (depending on their proximity to other grounded equipment) may actually cause the lightning to jump from the incompletely-grounded end of the short rod to the next closest grounded object. I've seen it happen before... if it's close to the surface, it can make for some wild, glassy soil samples. :) And if you can, please use copper strapping, or a GOOD Copper/Nickle braid - several years back (we had never noticed it before), I noticed that the guy cables on our 500' tower were originally grounded using 1/4" copper ground wire - bad idea... every leg was grounded, and the reason we never noticed that they were grounded this way originally???... the ground wire had vaporized and separated into tiny little chunks which ended up scattered in the field... no sign of the wire left at first glance - and the original ground rods were never exposed above soil level. Just in case you might have wondered why braid VS traditional ground wire: electricity travels across the skin of the wire, not so much in the core; more little wires woven together -- more surface area; known as the "skin effect." Although the skin effect is more relevant when dealing with Things like AC or High-Frequency RF, it still applies to the seemingly random actions of lightning.

Ok... I'll stop now. Maybe I was able to help with your initial question. sorry about all the fluff.

Hope all this helps!
Best Wishes and 73's!

Actually, I *did* find one of those things!

http://www.american-milspec.com/p961.html

Alas, it's a bit too tall for my use. I'm thinking of using a 26' whip
with a remote coupler (Harris RF-601) for operating from 40 through 15
meters. Or, I might go to a 30' whip for ops on 60 through 18 meters.
I haven't made up my mind yet although I'm leaning toward the 26' version.

If I go that route I might pick up a commercial, little brother of that
massive Navy style whip - the Shakespeare 5300. It's sold as a 28' whip
but it's actually 26' as they use the bottom two feet for a mounting
sleeve. It's made for shipboard use but is substantially lighter than
the Navy 35' whip. It's only 2-3/8" in diameter, for example..

Time is a precious commodity, at the moment, but I still might roll my
own from Texas Towers Aluminum.

From: Reg Edwards <g4fgq.regp@ZZZbtinternet.com>
Message-ID: <FNKdnffJiNqFI1bZRVnyrw@bt.com>
Source record: 55467

Roy, there you go again - confusing the issue by re-stating the bleeding obvious.

What happens to the ground wave AFTER it has been radiated is not relevant to the efficiency problem. (Which has now been sorted out anyway.)

The losses we are concerned with all occur in the near field. They are -

(A) Loss in the radials and loss in the soil in the vicinity of the radials, which is represented by Rradials. It is the input resistance of the radials. It can be determined by measurements. Rradials is the value used in the usual formula -

Efficiency = Rr / (Rr + Radials), which, in the present context, is incorrect.

(B) Loss in the soil surface and soil NOT in the vicinity of radials, but still in the near field, represented by Rsoil.

Frank, using NEC4, has managed to seperate losses A and B although not the resistance of Rsoil.

So, after finding a value for Rsoil, a more accurate formula is -

Efficiency = Rr / (Rr + Radials + Rsoil)

Where Rr is the radiation resistance referred to the base of the antenna.

Note that Rsoil cannot be measured but can be deduced from the actual efficiency. Both Rradials and Rsoil are functions of the same soil characteristics.

Reg,

Its Still a supported item by Harris. You can buy all the manuals from
them. This coupler is used just about on every Australian and American
warships

Theres plenty of these tuners on the surplus market.

Ontario Surplus sells them and have all the details on them, they dont
help customers who dont BUY Harris Stuff from them.

Columbia Electronics may also have manuals and information.

Murphys surplus in California sells this item.

You dont need the "GAS" to obtain the kilowatt rating, that tuner is
full of good "stuff" This tuner was mainly designed to be used with a
35ft on a ship. It can run a long wire with some limitations. It
probably can take more than a kilowatt, however it depends what kind of
antenna you have.

I would buy it, and try and complete the complete Harris lineup. This
stuff is great, the quality is overwhelming.

Good Luck

Pat

Just look in the ARRL hanbook and use their 40 meter beam elements. They
self supporting and have a wind rating of 90mph. In a vertical
configuration with guys they would never blow down in a 100 years.

Dont forget the Navy Whips by valcom etc were designed to take a take from a wave etc. Tons of water would bend any noodle. They really a overkill. Some were also designed to take shock blasts from canons etc and fatigue from 20,000 rounds weakening the metal.

Theres a lot of Yagi element stress element software around, i would use it and design it to your spec. I would make sure you use 6061 which is the most corrosion resistant and has the most strength. Array Solutions sells element stress software from some Ham Kurt Andress or something like that. ON4un also has some free software with his latest book.

How you gonna tune this beast on all bands? Would be interested to hear how you going about this.

Pat

You can do it with dipoles, like the HAARP transmitter. It has the most gain per acre than any other antenna. You can really use any antennas, just the phasing becomes complicated. You need to ensure all antennas are identical and have the same impedance and reactance etc etc.

Its a bloody complicated exercise to design such an array. Look up the varios web pages on google.

The DF arrays used around the world are receive only versions of these antennas. Look up "super resolution DF arrays. They amazing stuff!

A number of ANtenna companies sell wide band vertical arrays for transmitting. They consist of 12 vertical in a circle with a radiator in the centre. They then have a smaller inner circle for the higher frequencies.

I would like to pick up one of the Super DF arrays one day on the surplus market, oh boy what fun you can have! They can work out the location of a station with one DF receiver. Called single station Location.

Beam forming on receive and transmit are the same thing in reality. However its not as easy building phase stable antennas on transmit that cover 1.8 to 30 mhz.

If you work it all out and can do it for 500 dollars let me know. I would like to buy a beam forming antenna for shortwave receive. With cost of DSP chips dropping who knows maybe some day some smart ham will come up with a Super resolution cheap df system/ beam forming transmit system.

Ocean radar also use these complicated systems.

HF antennas for all locations RSGB has a article in their for beam forming using compact 1 metre loop antennas, you might want to check it out. Its a homebrew version of the Hermes Loop system. Same thing could be done on transmit with magnetic loops. If you took a ham 8 circle vertical array and substituted magnetic loops you could perhaps do it. You need someone smart like W8JI to figure out all the mathematics and details.

That does nothing for breakdown voltages to control cables unless the relays are a certain construction and wired a certain way. It can help with antenna end-to-end breakdown voltage.

no, you can't make antennas smaller this way... you can make small parts behave differently, but you can't get more gain or efficiency than a simillarly sized 'normal' antenna. i don't know of any hams actively working in this area, mostly because on hf the antennas get huge quickly. and on vhf/uhf and up there are much simpler ways to get gain for single point to point use that most hams are interested in. the real applications for things like this are radar and multi-point fixed or mobile systems that have to deal with multipath reflection and interference.

YEP!

You have to account for loss of battery power, loss of gain in the
semiconductors, etc. Or, provide a stable thermal environment.

High gain generally relates to large size.

"Rubber Ducky" antennas are low gain compromises.

There is no such animal as "High Gain Rubber Ducky" [pun intended]

i know i know. the factory one is a dual band 10" antenna (cb and noaa). i'm looking for the ~27MHz cb band antenna that is approx 12-18" long. this would have better gain than what i have now, but obviously not like a 1/4 or 1/2 wave antenna.

any suggestions on through-glass mini "loaded" cb antenna.

You should read Paul Lloyd (Lloyd Paul?) Verhage's long series of
"near space" articles which have been running in Nuts & Volts magazine
for at least a year! He started sending balloons and packages of
scientific experiments (radio telemetry and DF'ing, cameras, once
even included some roaches!) into near space years before that.

FWIW, he is a "ham", and when he started, he was a student here at
Kansas State University. Even better, he launched his balloons
from the "Johnson Near Space Center" about 10 miles south of Manhattan,
Kansas; so-called because Dr. Gary Johnson, K0HGJ, who was working to
duplicate some of Tesla's high-power experiemts, owned a humongous-
big-and-tall metal building with VERY-big sliding doors that was
perfect for inflating balloons inside (out of any wind) and carrying
outside for launching, and the similarity with the name "Johnson Space
Center" was just too good to resist!

I believe Lloyd (the name he used then) is now a high-school teacher
somewhere, and he incorporates his balloon launches into his science
classes.

Although I can't cite the reference (I read too many magazines from too
many sources), a recent article somewhere gave a fairly-definitive answer
regarding grounding vs. depth of ground. Since I don't plan on digging
any 35-foot holes (I vaguely recall that number from the article), I
didn't even file the article (or if I filed it, I can't find it now!-(

I used to do a lot of radiosonde work. Those balloons would go to
110,000 feet at times. The transmitters were small, probably not more
than a watt, but we tracked them with an automatic system. The instrument
used a 1680mhz transmitter with an upside-down ground plane antenna in
the bottom (I think that was the freq. but it was near there). The
tracking antenna, though, was a parabolic dish with a wobbling feed-point
antenna that automatically tracked the balloon's radio, giving us a
continual readout of azimuth and elevation angles. By combining this
data with the received data from the instrument's aneroid barometer,

temperature and humidity sensors, we could locate the balloon with good accuracy in three dimensions. Thus the run would provide temperature and humidity profiles as well as data on winds aloft. Balloons almost never go straight over you and when they do it is almost always early in the flight when the signal is close and strong.

> The OP hasn't told us the elevation angles of the locations of the

A lot depends on frequency, too. Tracking a 2.4 or 5.8 ghz transmitter is different from tracking a 35mhz transmitter.

Hi Pat

Actually the "Compact Quad" is meant to be fed by 50 Ohm coax through a 1:1 balun attached at the end of the open-wire matching section. Here the VSWR should be under 5:1 on the 40, 20, 15 and 10m bands. Of course you can also use open-wire line, but then the VSWR at the radio will depend on the length and characteristic impedance of the feed-line.

Found this illustative article about beamforming:

How to create beam-forming smart antennas using FPGAS:
http://www.embedded.com/showArticle.jhtml?articleID=60401726
Quote: "...The adaptive process permits narrower beams and reduced
output in other directions, significantly improving the
signal-to-interference-plus-noise ratio (SINR). With this technology,
each user's signal is transmitted and received by the base station only
in the direction of that particular user. This drastically reduces the
overall interference in the system..."

I believe I see an error in "Fig. 1" in that document. The text to the left states you need a" Copper pipe with a diameter of 10 mm and a length of 1480 mm". Correct. However, the diagram claims a length of 1480 mm from the top of the antenna to the top of the sleeve. Wrong! That length on the figure should be 975 mm and/or the diagram should have been drawn to show that the 1480 mm length is from the tip to the _bottom_ of the entire assembly.

Nicely done document.

1452. Size of horizontal loop?

Newsgroup: rec.radio.amateur.antenna
Date: 2006-07-29 16:53:53 UTC
From: Hans Remeeus <hans@remeeus.nl>
Message-ID: <4j1i51F5rquhU1@individual.net>
Source record: 55389

Dear all,

Next year we will move to another house with a yard of about 1 acre.
After 35 years of dipoles finally a horizontal loop is within reach!

My most used band is 80 meters for local and mid-European communication.
A few times a year I participate in an HF-contest, but I am not a kind
of DX'er.

I want to feed the horizontal loop with about 200 feet of 600 Ohm open
line and use the loop for multiband 160 - 10 meters with a balanced
antennatuner.

The height of the loop will be about 35 feet and I will use wooden
supports for the loop.

It am planning to make a full-size loop for 80 meters. However, on this
yard it is easy to make a loop of 4 x 100 feet instead of 4 x 70 feet.

What is your opinion about the size 400 feet instead of a full-wave for
80 meters?

Thanks!

Source record: 55390

Hans,

I don't think it's worth it. The patterns and ground loss of the two antennas at a height of only 35 feet are really very similar.

On the other hand, the impedance of the full wave loop according to EZNEC is going to be around 100 ohms resistive, while the 100 foot per side loop has an impedance of about 1500+j3200 ohms.

I'd recommend saving the extra 120 feet of wire for other antennas and just building the fullwave.

Now, if you want to use the antenna with a tuner at the feedpoint or perhaps open wire feed, the impedance of the 100 foot side loop on 160m is much more reasonable (64-j1300) than the 70 foot per side loop (EZNEC reports 8000-j30000! that is to say, infinite :-))

73,
Dan

Hi Reggie,

Of course it is incorrect, it is a definition of your own invention.

>Efficiency = Rr / (Rr + Radials + Rsoil)

This is merely an elaboration of the commonplace
Efficiency = Rrad / (Rrad + Rloss)
which you declared
>>is very much in error.

The error is yours, and your bafflegab that has flowed from this pronouncement of an "error" has been in an effort to cover your tracks. The wonderment you are met with is that you failed to acknowledge that Rloss is commonly accepted to mean more than Ohmic loss.

Reggie, the archive is rich with this discussion, and no one but yourself makes the mistake of presuming Rloss has ever meant to be confined to the Ohmic loss of the radiator's metal parts.

For anybody who can expound on the above question, I'd be interested in the effectiveness of such loops that are a small increase in size over a 80M full-wave size too, such as approximately 300 - 350 feet. I, too, am hoping for useful operation on 160, even though 80M is my primary interest.

Hi Hans,

An unnecessary change. Also, take care to anticipate that high
frequencies into a large antenna create many, many radiation lobes AND
nulls that may/may-not be useful.

Dan,

I believe the original poster DID indicate he would feed the loop with
600ohm line and a balanced tuner.

Could you also run the Z figures for my plan of using a loop of 300
feet of wire on 160? (1.9000 MHz) ... my height will be close to 50
feet, btw.

Tnx,

Hi All,

In this last regard, consult:
http://www.cpccorp.com/deep.htm

However, depth is not the end-all be-all of the subject. Protection
can be obtained for far less effort as any AM vertical antenna can
give evidence to with its radial system.

Ed,

517-j7600 for a 300 foot loop at 50 feet
still 110-j2500ish for the 350 foot loop at 50 feet.

This is a rapid fire thread!!

Good point on the multiband original post... didn't read carefully.
For 160 meters, the longer the better over an 80m fullwave. Richard
has a good point about multiband use but the extra length doesn't
change that caveat too much. If you've got an acre of land, it's
probably worth thinking about different antennas for the low bands and
the higher HF bands.

Hi OM,

The difference between an infinitesimal antenna and a quarterwave
antenna is only 5%. However, to get the small antenna to resonate
brings far more opportunity for loss. 12-18" long is not likely to
bring you any advantage but carefree dreams unless you can strangle
the loss.

Hi John,

As David and others offer, this adaptability and beamforming characteristic is a product of both massive duplication and a large area with respect to the wavelength of interest. To put it in rather more traditional terms:
"There's no such thing as a free lunch."

You ask about controlling small segments independently. Can you imagine that this maze of control wires would in itself be a more capable antenna? This is the price of complexity: if you can afford these elaborations in design, why not do it the traditional way? You gain nothing in sensitivity, you gain nothing in efficiency (which is most certainly the first characteristic to suffer by orders of magnitude). And to offer it as a prospective "stealth" antenna is defeated from the outset.

Think of a rather more practical example that is also a good metaphor. Imagine the Fresnel lens. It performs its beamforming through segmentation. Its advantage is that it is lighter than the complete lens, but if you can tolerate the weight, it offers nothing else to compensate for the elaboration of a complex set of lens segments piled one atop the other.

Now, if you can pay the price of elaboration, you can spread antenna elements about - disguised even. You can bury control cables and signal cables - you will certainly need them both. You can devise a control program to "focus" the antenna - which is what beamforming is all about. OR you can twist knobs like the thousand armed Shiva to achieve the same thing. For some, this technical challenge alone is worth the struggle - forget the DX. And yes, you will actually gain an advantage over a single fixed antenna.

Try with the four square antenna which encompasses all these topics that interest you. If you can wrestle with the knots of its complexity, you can step up to more sophisticated issues.

Yeah, Ed, I certainly don't mind doing a few quickie models here and there, happy to do it.

It's worth ordering it, though, when you want to do something like I did and model the pattern of your your five element 2m beam 16 inches below your 6m moxon rectangle in the presence of your HF doublet and a nearby aluminum roof, and generate the pattern for eight azimuth directions.

It's a great tool to have if you like building antennas, especially if you have complicated, site-specific improvements you might want to do.

[Not sure you are asking me or Sal about this but I'll answer for me.]

Same way the Navy does it! With a Harris RF-601 remote antenna coupler.
Only way to go in my view..

But, for the record, I'm not planning on using it on all bands -- only
on the bands where it has some chance of being an effective radiator.
That's why I'm thinking of either 30' (60 thru 17 meters) or 26' (40
thru 15 meters).

I am currently trying out a horizontal loop on my roof. I live in the trop floor flat and have a 21' x 24' rectangular flat roof with a 3' parapet (low wall) around. The roof is some 30' above ground.

I have draped a 21' X 24' loop of wire aroiund this parapet and fed to the tuner with just 6' of 600 ohm ladder line. The tuner is an SGC SG-230 laid on the roof and has its feed cable (combined coax/control/power cable) wound as a choke balun. The tuner is effectively acting as a balanced drive.

Results so far.
1. The natural resonance is a little below 40M
2. I can match on all bands from 160M to 10M.
3. It is definitely acting as an NVIS on the LF bands.
4. It works better on LF at night. This could be due to the radiation going upwards and ionosphere reflects LF at night.
5. It acts like an inductive loop pick up for any QRM amanating from the house.
6. Efficiency is generally low. Lobes are all over the place on the HF bands.

I will try and raise the loop a foot or two above the parapet tomorrow and see if this helps. Otherwise I am not impressed!
I used to get better results with a 30' vertical wire on a fibreglass fishing pole. Unfortunately I don't hasve a good ground for a vertical here and the vertical would cause problems with the local planning authorities.

If I can't find a way of making it work better on 80M and 40M I will probably resort to a very short loaded dipole diagonally across the roof.

Maybe somebody knows for sure, but I think BPL starts above the broadcast
band. On the other hand, DSL uses lower frequencies, up to about 1000 KHz. I
would not expect to have DSL leakage to sound like hum, though.

Hi Reg,

By any remote chance have you read any of the posts that followed the one you initiated in 'radial attenuation', just below the one we're in now?

If not, please do so, and then savor the crow on your plate concerning your somewhat 'stiff' position on BLE's failure to determine the ground characteristics that lie beneath the radials.

Thank you.

Thanks to all for your nteresting information!

This evening I found another interesting site about large horizontal loop antennas, including a very simple but effective tool. It can be found on http://www.smeter.net/antennas/rjeloop4.php

I will make a horizontal loop of 4 x 25 meters (= 4 x 82 feet) for 160 - 30. And for the higher bands a 14 MHz full-size vertical delta loop. Both with open feeder line.

> pressurise with nitrogen to achieve full specs of 1KW average power?

Here's a quote from the manual:

"The fan and case form a heat exchanger which is used to dissipate the heat produced by inductor 1A2L1 (heat producing element). The fan circulates the nitrogen atmosphere over and through the inductor, and then through the air duct between the bottom of the case and the chassis. The heat is transferred to the nitrogen as it passes over the inductor, and then from the nitrogen to the case as it passes through the air duct. The heat is transferred from the case to the outside air and mounting structures by a combination of conduction, convection, and radiation."

Keep in mind that the coupler is rated at a kilowatt continuous duty in harsh environments. If your circumstances are kinder and gentler to the equipment you might get away with using pressurized dry air. Me? I use nitrogen.

I'm not sure of the controller on the 2601. (I have the RF-601 and the coupler unit itself looks identical to the 2601.) On the RF-601 you can run in automatic mode with an appropriate Harris transmitter (RF-350K, etc.) or you can run in Manual mode where you directly control the tuning. This means you can use the coupler with virtually any source of RF, even ham gear. I think this is what you mean by 'stand alone installation' and, if so, the answer is yes.

Harris gear is excellent -- among the best in the world. Buy that thing before someone else gets it..

dunno how much of it you have, but if it's so old all the markings are
not vis on it's entire length i would have it swept just to be sure
it's actually ok"" for what u need it for

sometimes stuff that is new /looks good etc dosn't work at all or only
to certain freq's

but if you just want connectors rather than toss it, buy some
connectors for cheep on ebay

they are many long time coax vendors such as cable experts send them a
small piece ask them if they have connectors and sure they would tell
u type be surprized if they didnt know it!!

good luck

i've read the specs on some healiax and lmr 400 but i can't say that i always can interpert it fully and confused myself basically interperting a real world practical answer

if for ex i am going to do some 1296 work and debate what coax is best

i compare lmr400 to 1/2i heliax is the heliax much better ? by how much

how about lmr 600 vs 1/2in/ and maybe 7/8" heliax is the lmr nearly as good or is the heliax vastly superior?

comming here for a tie breaker everyone i asked either gives different answers and non can explain their choice

i am not looking for a well lmr is pretty close and cheeper so buy it, price is not the issue i just want to know based on technical spec's

if they are only 1db apart it's splitting hairs i'd get the cheepest easist to work w/ after that i just want least loss

thanks

> that wasn't viable at the time.

i don't think tossing goax into a jar would protect you , dunno

but it's good to have a arrestor the good ones have almost not
appreciable loss that you would notice on a scanner

it will protect it from misc static sudden bursts which u might not
unplug fast enough if your luckey

it might reduce staticand improve reception

couldn't hurt i use some arrestors but when i am not using the ant, i
unplug outside the house and ground it it's a choir but i am nutty

the other alternative is radio insurrance pretty cheep for just a
scnnner naturally it would 'protect' humans

best luck

I assume that when used on higher frequencies where the antenna is more
than 1/2 wave long, the relay contacts are to be closed.

If that is what you want to do, and if the higher frequency bands are
even multiples of the lower frequency, then you could connect the ends
of the 1/2 wave antenna to a shorted 1/4 wave stub made out of open
wire. At the lower frequency this would place a very high impedance
between the two ends of the antenna, and at even harmonics where the
stub would be an integer number of 1/2 waves long, it would place a low
impedance between the antenna ends. Cheaper than a relay, too.

The problem you are having comparing heliax to coax is that you are not considering all the parameters. Loss is only one aspect. The biggest difference between most coax and Heliax is physical construction. Heliax, properly installed, with last 10 to even 20 years outdoors before it should be replaced. Coax would deteriorate much much faster. Heliax is a much more "sturdy" product and can also hold up to weather damage better than coax. Being made with a sold jacket also adds to its shielding superiority over most coaxial cables.

For most ham use, You'll get the performance you need with coax type cables and not need heliax.... plus your wallet will remain fatter, too. (I haven't even mentioned the high cost of connectors for Heliax, if you purchase them new.)

Think about that above statement. Do you really think that a lighting strike capable of traveling hundreds or thousands of feet in the air is going to be detered by a couple millimeters of glass, or a couple inches to the opening?

No doubt you'll get a few answers...

This is a good URL to compare line loss on;

http://www.ocarc.ca/coax.htm

A 50 metre run on 1296 of LMR400 is about 7.8dB

A 50 metre run of LDF4-50 (1/2" heliax) is about 4.2dB

A 50 metre run of LDF5-50 (7/8" heliax) is about 2.3dB

You can work out the difference in your install by scaling things
proportionally. Dont forget to factor in additonal loss for any mismatch.

You then have to ask whether that few dB will make a difference in
whatever your mode of operation and interest is. When a RX signal is
borderline that dB or two can make a useful difference.

Dont forget to factor in the cost of connectors. You may also find both
the LMR400 and Andrew cable is too rigid.

I'd personally stick to LMR400 simply because I see that as a major step
up from (say) RG213 (16dB loss per above) using roughly the same cable
diameter. Some of my interest is in low signal 144MHz work but I tend to
reduce that problem by using a preamp at the antenna. About the only
downside for me using LMR400 is its rigidity and turn radius limitation.
I also tend to think in terms of a link budget. Thats easy to do with a
path prediction program. (There are some GPL ones out there)

Hope this helps

I'm seeking a 4:1 balun design that could handle >10 watts efficiently on 20M and would be easy to reproduce without purchasing special ferrite cores, etc.

There's an old design that puts an electrical half wave of coax between the two connectors on the balanced side.

What drawbacks does this old design have compared with more modern ones? Suggestions would be appreciated.

There is an air core balun described in Hints and Kinks 12th Edition
12 trifilar turns (three wires of identical length) of #12 or 14 ecw
close wounds on a 1 inch od form. It's a 1:1, but I would think that
you could try experimenting and produce a 4:1 without too much trouble.

The coax baluns can be heavy and cumbersome -- a simple ferrite bar
could be used in lieu of a core. Cores are readily available at most
radio wholsalers. For 20 watts you could build a very small but
effective balun,

This does not fully answer your request but may put you on the
right track. You might find some in the newer antenna books.

As with stubs, it is frequency dependent and therefore is
limited to a single band. One advantage of a toroid-based
transmission line transformer is that it is broad-banded
often covering a 10:1 frequency range. If you confine it's
use to 20m, the "old design" should work well enough.

It's not a new idea. In a previous life, I worked on the AN/FPS-85 spacetrack radar at Eglin AFB, Florida. This was 1967-68, while it was undergoing acceptance testing. It's a computer-controlled phased array radar with over 5000 separate transmitters and over 4000 separate two-channel (for V and H polarization) receivers, each with its own antenna. At the time, it was controlled by a pair of state-of-the-art IBM 360/30 computers(*). The one I worked on was actually a replacement for an earlier one which was built beginning in 1962 but burned to the ground just as it was completed. (You should have seen the fire control system in the new one!) Radar is, of course, ideally suited for adaptive beam forming, and steering, since both transmitter and receiver are controlled from the same point. The original had some sort of analog variable delay lines, but the replacement had delays switchable by diodes in binary weighted increments. Transmitter and receiver beams could be changed in shape and of course direction, and the receiver beam could be split into several to aid tracking. I believe it's still in use, but undoubtedly with much more capability due to upgrades (see http://www.swri.org/3PUBS/BROCHURE/D10/survrad/survrad.HTM) and the vastly greater computer power now available.

If you're interested, there's more about it at http://www.globalsecurity.org/space/systems/an-fps-85.htm and http://www.fas.org/spp/military/program/track/an-fps-85.htm, or you can do a google search of FPS-85.

Roy Lewallen, W7EL

(*) Apparently the IBMs had a limited amount of non-volatile memory. When the power failed, the programs had to be reloaded. This required about a day of feeding boxes and boxes of Hollerith cards through the reader.

> the loss.

To clarify, that 5% is only for a lossless antenna. When the antenna becomes very short, you also take a beating in conductor loss, since the currents get enormous, so the antenna itself becomes inefficient. And of course if the antenna depends on current through the ground, you take a beating there for the same reason. So add conductor and possibly ground loss to the inevitable loss in the matching network which must also deal with high current and/or high voltage.

> Reg,

This is fairly trivial Reg. It takes me about 90 seconds to run
the program, analyze the data, and record the results for
each length. I consider this a learning experience. Some
of your requests have forced me to read the NEC manual
and other books I have on modeling.

As a preliminary run I have gone overboard, just to see the
overall trend. The fact is I see nothing dramatic happening
until the radial gets very short. Possibly you can see

regions where I need to concentrate. Obviously most of the steps are very large, and I may have missed something. I would have expected to see a phase reversal though.

9m Zin = 101.8 + j 21.7
8m Zin = 100.5 + j 21.5
7m Zin = 100.5 + j 19.0
6m Zin = 105.1 + j 17.8
5m Zin = 110.5 + j 26.1
4m Zin = 97.0 + j 40.2
3m Zin = 70.5 + j 25.9
2m Zin = 67.2 + j 19.6

I did try steps of 0.1 m from 8 m to 6.7 m, and saw nothing but a progressive trend.

Frank

Hi Tom

If you are interested, I have about 20 new ferrite toroids that arent marked. I wouldnt mind constructing a couple bifilar, 4:1 baluns and connecting them back to bact for loss measurement at 14 MHz. If the prototype works well enough, I could easily measure them at other frequencies from about 5 MHz to 450 MHz.
The cores are 1.9 inch OD and 1.4 inch ID and 3/8th thick. I'd expect one toroid to be adequate for power levels around 20 watts. That could probably be estimated after the loss is measured.

So, if you are interested, I'll give you a couple cores after I make some measurements on a prototype.

I'd do a little research on web published information before building the prototypes.

I have build alot of baluns for higher frequencies, but I cant make power on any band.

Jerry

Again, I am not interested in selling. HAM stuff is my fun time.

That's outstanding! I see the original antenna was only about 15% efficient
and the capacitance hat improved it by about 2 dB. I will play with that
program. Thanks.

Don't worry theres no "magic" or secret designs when it comes to
helical antennas.

The Q of such close wound loading is so poor that it barely matters if
you place it near the center or the top. This would be the preferred
positions rather than at the base. However if you do want to stick with
helical winding try and get rid of some of the inductance using a
capacity hat.

Quite frankly i would ditch the helical winding and use a properly
wound center loaded high q coil. You will gain 5 db over any helical
design. You can design such a antenna using the Mobile.exe program
that comes with the antenna handbook.

All my centre or 2/3rds loading coils beat my HyQ Screwdriver so badly
that it makes me want to cry. But thats what you have to pay if you
want arm chair band changing.

==========

Frank,

I'm pleased to hear this does not involve you in a lot of labour.

Thanks for the additional useful information.

Go back to program Radial_3 for a few minutes and insert our standard
inputs.

Set the number of radials equal to One.

Slowly vary length between 1 and 10 metres while observing Rin + jXin
of the radial system.

Vary length to find maxima and minima in the value of Rin. Max and
min are more pronounced at the shorter lengths due to lower
attenuation.

Remember, the radial (transmission line) is open-circuit at the other end.

There is a minimum of Rin when the radial is 1/4-wave resonant at 2.4 metres.

There is a maximum of Rin when the radial is 1/2-wave resonant at 4.8 metres.

There is another minimum of Rin, but less prominent, when the radial is 3/4-wave resonant at 7.3 metres.

As length and attenuation along the line increase, the variations of Rin about its mean become smaller. Eventually, of course, it converges on Ro, the characteristic impedance. (Ro is also computed but remains constant as length is varied.)

There would be a full-wave resonance at approximately 10 metres but it is damped-down into the noise by the attenuation of about 20 dB at that length.

Now, what I would like you to do is search for the maxima and and minima in Rin, with their lengths. using NEC4. At some places you may have to use increments of 0.1 metres.

If you find any max and minima the values of Rin + jXin will be different from my program and the lengths at which they occur may also differ. I would like to use the information to improve the accuracy of my program on the assumption that NEC4 is more correct when calculating buried radials.

(In this investigation, you may think it peculiar that lengths as small as 0.1 metres should be significant at 8 MHz. This is due to the very low velocity of propagation along buried radials. Program Radial_3 estimates VF.)

Reg.

My original balun from 30+ years ago was an airwound balun, commercially manufactured by B&W. It handled 250 watts AM from 80 through 10 meters.

If I recall correctly it was two bifilar wound coils, close spaced, about 10 inches long with the series parallel jumpers for 4:1 impedance ratio.

For good efficiency, use high-Q center loading coils.
That means a diameter considerably larger than the
diameter of the fiberglass whip.

Hi Tom

I use a Q section of 100 ohm "coax" (2x 50r cables side by side with shields joined at each end) on my 20m single loop quad (about 140 ohms modeled) I went for the higher load Z (200r) because I wanted a higher SWR b/w and the possibility that it might work on odd multiples (not that there is an amateur band on 42MHz! - Thinking about a 30m version)

It seems to work well but it isnt as if I have made any serious comparisons. Its 2:1 SWR b/w is something between about 13.5 and 15MHz.

All you need is coax and allowance for velocity factor!

Dont know about the balance/unbalance side of things so much. I was getting some shack radiation that a choke balun (turns of coax on an air core) where the feed met the Q didnt seem to help much. The antenna itself is only 8-10m from the shack anyway.

I can send you the modeled details if you like.

Cheers Bob VK2YQA

------------ REPLY SEPARATOR ------------

I've done it myself and been quite happy. I used a low RPM reversible
DC motor to tune it remotely from the shack. Works great.

The only suggestion I would make is to not tune it with any
significant power to it or you could damage the coil by arcing as the
roller moves along. Up to ten or twenty watts should be ok. Keep the
roller clean.

1dB is a human-detectable change.

2dB could make the difference between a QSO and no QSO with marginal S/N ratio.

1 "standard" S-unit of 6dB can probably make the difference between marginal S/N and armchair copy.

If copy is already armchair, Reg's totally right. No change. I like to make a lot of QSO's that are down in the noise, though.

If the voltage and current are in phase at every point up
and down a transmission line (with a resistive Z0), there
are no reflections. If there are reflections, the voltage
and current are in phase only every 1/4 wavelength.

> Which book is best for learning about concepts like
> antenna,reflection,swr, etc. I am working only at hf band. If there is
> any online tutorial ?

Unfortunately, only the older (pre 1990's) ARRL Antenna
Books present a decent explanation of reflections. The ARRL
has stopped discussing forward and reflected waves and
started discussing impedance matching. IMO, it's part of
the dumbing down of the ARS along with the rest of the US.

Walter Maxwell literally wrote the book on "Reflections". His
web page is: http://www.w2du.com Worldradio magazine is on
the verge of publishing "Reflections III". Their web page
is: http://www.wr6wr.com

You might get something useful from my Worldradio magazine
article available at: http://www.qsl.net/w5dxp/energy.htm

A good design process starts with brainstorming unfettered by practicality. The next step is to take those ideas and start applying filters to the set of ideas you came up with in the first place, and to turn a more pragmatic eye toward the realities of those ideas.

In a thread like this, I think that people chime in on different steps of this process. With something like adaptive beamforming, which is not a new idea, a lot of the practicalities have been hashed out and a lot of people already know about them.

I think it's worth avoiding the interpretation of responses as reflecting on one's abilities or character or intelligence. Richard is good at pointing out in some detail why a very hard problem is very hard.

After that incident, I read many articles concerning grounding ham equipment, the home, the towers and the antennas. They seem to be different systems, but one thing I learned and most agree on is that the lightning arrester on the coax needs to be one of the chemical versions and not a vanilla gap type arrester.

Actually, it wasn't lightning around at that time. the sparks were
static burst or something generated from lightning afar off. I was
concerned about the possibility of fire when I threw the connector
into the jar.

Hmm... maybe "like" is the wrong word...

Whaddya mean, QRP?? I'm running 100W into my 40m dipole on 20m with 100 feet of RG-58! Only 13dB of loss there! That's only 2 and change in S units. I mean, 100W/10^(1.3) = 5.01W... uhoh.

Seriously though, a lot of my 6m DX QSO's on CW are within a couple dB of being unreadable, I bet. Probably none on HF right now that could be split this finely, because all my tough ones are being covered by static crashes on 40 and 30m. Back when 15-10m were open, though, I would have welcomed a "1/3 S-unit" increase on some of the hard stuff.

Of course, fading is much more than 2dB, but having the average signal level that much higher will still make an *improvement* in readability.

That certainly could have been charged particle static
buildup. I experienced a similar thing in the Arizona
desert when the wind was blowing under clear sky, low
humidity conditions.

NO-CODER LICENSE APPLICATION and EXAM

(Simplified test approved by all book and magazine publiher and
VE whorehou$e$ who $ay "We need more ham$")

Please PRINT (that means no squiggly lines)

YOUR NAME (what they call you)
_____

ADDRESS (where you live) _____

BIRTHDATE (when you were born) _____

EXAM

Instructions: Make a circle (one of these round things O) around the
letter of the best answer! This is so we know what your answer to the
question is!

1. You TALK into a microphone with your _____.

A. Hands
B. Feet
C. Toes
D. Mouth
E. Armpits

2. When you talk into a microphone, you talk into _____.

A. the front
B. the back
C. the top
D. the bottom
E. the wire

3. "HEADPHONES" are worn over the _____.

A. Knees
B. Eyes
C. Toes
D. Ears
E. Lips

4. What do you do with the AC line cord coming out of a power supply?

A. Hold it in the air to pick up signals
B. Pull on it to start the motor

C. Talk into the plug to get real "skip DX"
D. Hook it to your antenna
E. Insert the plug into a source of power

5. A ?two meter? radio is:

A. twice as strong as a one-meter radio
B. two one-meter radios in series
C. a CB with two meters on the front panel
D. a good doorstop
E. yo mama

6. A "ten-foot mast" is how long?

A. Ten feet
B. Ten pounds
C. Two meters
D. Tree-top tall
E. yo mama

7. A ?Triband antenna? is made to work on how many bands?

A. 1
B. 2
C. 3
D. 4
E. 10

8. The ?Marconi? antenna is named after:

A. Marconi
B. Mantovani
C. macaroni
D. Dean Martin
E. yo mama

9. What colors of DIODES can you buy at a Radio Shack store?

A. Red, blue and black
B. Red, yellow and green
C. Orange and brown
D. I am colorblind so this is a discriminatory question and I should
automatically get my license because you have been mean to me.
E. I have no intention of ever using DIODES, so I should get my
license for free.

10. What color of SLURPEE can you buy at 7-11?

A. Red, blue and black
B. Red, yellow and green
C. Orange and brown
D. I am colorblind so this is a discriminatory question and I should
automatically get my license and free slurpees forever because you
have been mean to me.

END OF EXAM.

YOUR SIGNATURE (slap yo tag here)

Scoring:

Get THREE correct and you get an EXTRA!!!!
Get TWO right and you get an ADVANCED!!!!
Get ONE right and you get a GENERAL!!!
Blow them all? Just blow the VE and get any license you want!!!

thanks very much i see the 600 and 1/2 are very close and the 600 is
way chubby and hard to work w/plus $$ whereas heliax i think i can find
on ebay or hamfair

normal sized guess it will last has good shield not too bad to work w/
i think in my applicatioin a 1'x1' shaft few bends on the roof easy
and a few in the hallway molding tray prob the hard part :)

not counting hoisting it up the shaft the lmr went up ok but it's
light

adding more coax and antennas are the most fun

thanks again al for the help

The way my HOA enforces it is to levy a $200 fine in the form of a Mortgage impound on the first violation, with an increasing fine every two weeks thereafter.

Cec,
With a generous standard error of 1dB in the measurements, and taking
the 3-sigma limits, anybody who has claimed a crown on the strength of
1/3 of an S-unit should be obliged to hand it back to the judges
pending the other participants clamour for a re-count. ;o)

Reg.

1522. Re: High voltage switch/relays for antenna?

Source record: 55359

Thanks for the input, everyone. Here are my comments:

Power will not be the largest issue here. It will be the high voltage,
which will be approx. twice the max. end voltage of a dipole (while one
end is at highest pos.V, the other is at highest neg.V). Using a relay
will also pose a problem with arcing over to the relay coil and the
control cable.

In view of this I was hoping someone might have alternative
suggestions, such as a home-made, remotely controlled HV-switch. For
example, a motor that could use a screwing mechanism to close a contact
or to open it - up to a few cm/in gap.

There are some suggestions to use a 1/4 wl stub, where opening at one
end would pose a zero impedance at the other. But won't I still have
the same problem with high voltages - simply moved to the end of the
stub instead at the antenna gap?

Again - thanks for the input and feel free to contribute further.

73 - TF3KX

Try these links:

http://en.wikipedia.org/wiki/Smith_chart

http://en.wikipedia.org/wiki/Reflection_coefficient

Don't feel too bad if this subject is not too clear. It used to be
introduced in about the fourth semester of Electrical Engineering, usually
in Complex Circuit Analysis.

Here's the $2 version:

Impedance is a complex quantity (i.e. it has both Phase and Magnitude.) The
reflection coefficient is a measure of how well a load is matched to its
source impedance; the match determines how much power is reflected by the
load. Whatever is not reflected, is absorbed by the load. In the case of
an antenna, the "load" is free space; therefore all power absorbed by the
load is radiated into free space. We would like the reflection coefficient
to be 0; when that happens we have a perfect match and all power is
radiated.

Like impedance, the reflection coefficient has both a phase and a magnitude.
When most people talk about the reflection coefficient, they only conside
the magnitude and not the phase.

Actually, if there are reflections, the voltage and current ar NEVER in
phase.

In fact, voltage and current in the reflected wave are ALWAYS 180ï¿½ out of phase, while in the forward wave they are always in phase. Thus, along the line they alternately add and subtract, first reinforcing and then cancelling each other at every quarter wave, to form the standing wave.

I have a confession to make, Reg. I noticed precipitation
water from the fog dripping from everyone's coils when
the measurements first started. I waited until last when
the sun was shining and won the shootout. :-)

So how does a 1/2WL piece of transmission line driving a
50 ohm load wind up with the voltage and current in phase
no matter what the SWR?

All true, Walt, but I think we are discussing the net voltage
and net current which are in phase only every 1/4 wavelength
where the SWR circle crosses the horizontal purely resistive
line on the Smith Chart.

US Coast Guard is involved in the evacuation of US citizens in Lebanon
at the Port in Beirut. However, I'd like to see the source of the above
claim about CW.

Agreed. What appealed to me was that the difference was so easily calculated with your program. I simply reran the program with the hat reduced to miniscule size and observed the difference.

This was an AM broadcast station (Armed Forces Radio Service), so the difference was not likely to have been audible. The tech who put the hat on the whip may just have been making it easier to match. It was forty years ago.
